Running title: Invariant faces associated with a cone-preserving map

ON THE INVARIANT FACES ASSOCIATED WITH A CONE-PRESERVING MAP

BIT-SHUN TAM AND HANS SCHNEIDER

ABSTRACT. For an $n \times n$ nonnegative matrix P, an isomorphism is obtained between the lattice of initial subsets (of $\{1, \cdots, n\}$) for P and the lattice of P-invariant faces of the nonnegative orthant $\mathbb{R}^n_+$. Motivated by this isomorphism, we generalize some of the known combinatorial spectral results on a nonnegative matrix that are given in terms of its classes to results for a cone-preserving map on a polyhedral cone, formulated in terms of its invariant faces. In particular, we obtain the following extension of the famous Rothblum Index Theorem for a nonnegative matrix: If A leaves invariant a polyhedral cone K, then for each distinguished eigenvalue λ of A for K, there is a chain of m_λ distinct A-invariant join-irreducible faces of K, each containing in its relative interior a generalized eigenvector of A corresponding to λ (referred to as semi-distinguished A-invariant faces associated with λ), where m_λ is the maximal order of distinguished generalized eigenvectors of A corresponding to λ, but there is no such chain with more than m_λ members. We introduce the important new concepts of semi-distinguished A-invariant faces, and of spectral pairs of faces associated with a cone-preserving map, and obtain several properties of a cone-preserving map that mostly involve these two concepts, when the underlying cone is polyhedral, perfect, or strictly convex and/or smooth, or is the cone of all real polynomials of degree not exceeding n that are nonnegative on a closed interval. Plentiful illustrative examples are provided. Some open problems are posed at the end.

1. Introduction

This is the fourth of a sequence of papers studying the classical Perron-Frobenius theory of a nonnegative matrix and its generalizations to cone-preserving maps in the finite-dimensional setting from a cone-theoretic viewpoint, which is a geometric appro

ach as opposed to the traditional graph-theoretic (combinatorial) approaches (cf., for instance, [Rot] and [J–V 3]). The first three papers in this sequence are [T–W], [Tam 3] and [T–S 1]. Different fundamental aspects of a cone-preserving map are considered, one in each paper of the sequence — the Collatz-Wielandt sets (or numbers) in [T–W], the distinguished eigenvalues in [Tam 3], the core in [T–S 1], and the invariant faces in this

paper.

In [T–S 1], the preceding paper of our sequence, we studied the core of a cone-preserving map A, i.e. the convex cone $\text{core}_K(A) := \bigcap_{i=1}^{\infty} A^i K$. We were able to characterize the K-irreducibility or K-primitivity of A in terms of its core, and also to obtain many interesting results that give connections between the core, the peripheral spectrum, the Perron-Schaefer condition and the distinguished A-invariant faces of K. (We shall define some of these terms later on.) Nevertheless, the results we obtained directly or indirectly suggest that the set $\text{core}_K(A)$ does not capture all the important information about the spectral properties of A. In particular, if $\text{core}_K(A)$ is a polyhedral cone, then it does not contain any distinguished generalized eigenvectors of A other than eigenvectors. Thus, the index of the spectral radius of A cannot be determined from a knowledge of its core. On the other hand, in the nonnegative matrix case, as is known, the index of the spectral radius or of a distinguished eigenvalue can be described in terms of its (equivalence) classes (of communicating states). Moreover, we found, in a preliminary study, a close connection between the classes of a nonnegative matrix and its associated invariant faces (of the corresponding nonnegative orthant). This motivates our present study of the invariant faces associated with a cone-preserving map.

2

Here we would like to stress the differences between our work and that of others on positive (linear) operators. So far, the deepest results in the theory of positive operators are mostly obtained under the assumption that the positive operator under consideration is irreducible or the underlying space is a nice space, such as a Lebesgue space or, more generally, a Banach lattice. Furthermore, many of these deep results have no counter-parts in the finite-dimensional setting. A look at the monographs [MN 2], [Scha] or the recent survey paper by Dodds [Dod] will give the reader some ideas. (See also [Zer] for an earlier survey.) Over the past two decades, progress in a large part of the theory has followed three principal themes, namely, the kernel representation theorem of Bukhvalov (1974), the compact majorization theorem of Dodds-Fremlin (1979) and the spectral radius theorem of de Pagter (1986). These results are given in the settings of the familiar Lebesgue spaces or of a Banach lattice and, as can be readily seen none of them have a finite-dimensional counter-part, as their conclusions (that a certain operator is compact or is a kernel operator) are trivially satisfied when the underlying space is of finite dimension.

Nevertheless, the recent development of the combinatorial spectral theory of nonnegative matrices (applied to the reducible case which is much more complex than the irreducible case, see for instance [Schn 3]) has had some impact on the theory of positive operators. For instance, many of the graph-theoretic ideas (such as the concepts of classes, the notion of accessibility between states or classes) or of the combinatorial spectral results (such as the Nonnegative Basis theorem and the Rothblum Index theorem) of a nonnegative matrix, implicit in the early work of Schneider ([Schn 1]) and formulated first by Rothblum [Rot], have already been extended, first to the setting of an eventually compact linear integral operator on $L^p(\Omega, \mu)$, $1 \leq p < \infty$, with nonnegative kernel (see [Nel], [Vic 1, 2], [J–V 1]), and then to the setting of a positive, eventually compact linear operator on a Banach lattice having order continuous norm (see [J–V 2, 3]). Their treatment, which employs mainly functional-analytic methods, is made possible

3

by a decomposition of the positive operator under consideration in terms of certain closed ideals of the underlying space in a form which directly generalizes the Frobenius normal form of a nonnegative reducible matrix. In this work, we are also generalizing theorems on reducible nonnegative matrices. However, we shall not generalize the Frobenius normal form; indeed, we do not expect there is a natural generalization for a cone-preserving map when the underlying cone is a general proper cone. Our focus is on the invariant faces, and our results are geometric and provide new information in finite dimension. Moreover, we do not confine ourselves to a lattice-ordered cone, which in the finite-dimensional setting reduces to the classical nonnegative matrix case.

We now describe the contents of this paper in some detail. Some necessary definitions and preliminary results are collected in Section 2.

For a nonnegative matrix, we have the known concepts of basic classes, distinguished classes, initial classes, etc. In order to find for a cone-preserving map the appropriate analogs of these concepts, in Section 3 we begin our investigation by studying the lattice of P-invariant faces of $\mathbb{R}^n_+$ (the nonnegative orthant of $\mathbb{R}^n$) associated with an $n \times n$ nonnegative matrix P. We introduce the combinatorial concept of an initial subset (of $\{1, \cdots, n\}$) for P. An isomorphism is found between the lattice of initial subsets for P and the lattice of P-invariant faces of $\mathbb{R}^n_+$, thus relating a combinatorial concept to a geometric concept via algebraic structures. In particular, under this isomorphism a P-invariant join-irreducible face which contains in its relative interior a generalized eigenvector of P corresponding to $\rho(P)$, the spectral radius of P, corresponds to an initial subset determined by a basic class. This isomorphism motivates the subsequent attempts in this paper to generalize many of the known combinatorial spectral results on a nonnegative matrix that are given in terms of its classes to results for a cone-preserving map, formulated in terms of its invariant faces. In the course of establishing this isomorphism, we reprove the well-known Frobenius-Victory theorem, introduce the concept of a semi-distinguished class for a nonnegative matrix,

reformulate the known nonnegative basis theorem for the generalized eigenspace corresponding to a distinguished eigenvalue of a nonnegative matrix and offer a cone-theoretic proof.

The following are two of the well-known results on the combinatorial spectral theory of a nonnegative matrix that we wish to extend in this paper.

Theorem A. (Rothblum Index Theorem) [Rot, Theorem 3.1(2)]   *If P is a nonnegative matrix, then there always exists a chain of ν basic classes of P, where ν is the index of $\rho(P)$ as an eigenvalue of P, but there is no chain with more than ν basic classes.*

Theorem B. ([Schn 1, Theorem 5] or [Schn 3, Theorem 6.3])   *If P is a nonnegative matrix, then the Jordan canonical form of P contains only one block corresponding to $\rho(P)$ (i.e. $\dim \mathcal{N}(\rho(P)I - P) = 1$) if and only if any two basic classes of P are comparable (with respect to the accessibility relation).*

In our investigation, we find it useful to introduce the concept of the spectral pair of a face relative to a cone-preserving map. We do this in Section 4. Given an $n \times n$ complex matrix A, for any vector $x \in \mathbb{C}^n$, we assign to it an ordered pair $(\rho_x(A), \mathrm{ord}_A(x))$, where $\rho_x(A)$ is the local spectral radius of A at x and $\mathrm{ord}_A(x)$ is the order of x relative to A, a new concept which we introduce as an extension of the usual concept of the order of a generalized eigenvector. We denote this ordered pair by $\mathrm{sp}_A(x)$ and refer to it as the spectral pair of x relative to A. If A leaves invariant a proper cone K and F is a face of K, we observe that the spectral pair $\mathrm{sp}_A(x)$ is independent of the choice of x from the relative interior of F. This constant value is denoted by $\mathrm{sp}_A(F)$, and will be referred to as the spectral pair of F relative to A. Fundamental properties of spectral pairs of faces (or of vectors in the underlying cone) relative to a cone-preserving map are derived. One consequence is that we obtain a class of A-invariant faces of K given in terms of spectral pairs and the lexicographic ordering defined between ordered pairs

of real numbers, which extends and refines in the finite-dimensional case the class of invariant ideals discovered by Meyer-Nieberg [MN 1] for a positive linear operator defined on a Banach lattice. We also prove several equivalent conditions for a distinguished A-invariant face, a concept which we introduced in our preceding paper [T–S 1] as an extension of the concept of a distinguished class of a nonnegative matrix. Then as a natural extension of the concept of a semi-distinguished class we call an A-invariant face semi-distinguished if it is A-invariant join-irreducible and contains in its relative interior a generalized eigenvector of A.

In Section 5, in terms of semi-distinguished A-invariant faces we formulate and establish a natural extension of the Rothblum Index theorem in the setting of a linear mapping preserving a polyhedral cone. We also give examples which show that in the nonpolyhedral case the result is no longer true.

We take a closer look at semi-distinguished A-invariant faces in Section 6. Further properties of invariant faces (mostly involving spectral pairs, semi-distinguished invariant faces, or distinguished generalized eigenvectors) associated with a linear mapping preserving a polyhedral cone are obtained. It is proved that if A leaves invariant a polyhedral cone K, then a nonzero A-invariant face F of K is semi-distinguished if and only if for any A-invariant face G properly included in F, we have, $\mathrm{sp}_A(G) \prec \mathrm{sp}_A(F)$, where $\prec$ denotes the strict lexicographic ordering between ordered pairs of real numbers. The nonpolyhedral case is also examined in detail. It appears that whether a cone-preserving map shares some of the properties of a cone-preserving map on a polyhedral cone depends much on the geometry of the underlying cone. In particular, we prove that if A leaves invariant a proper K which has the property that the dual cone of each of its faces is a facially exposed cone, then the above-mentioned characterization of semi-distinguished A-invariant faces in terms of lexicographic ordering still holds.

In Section 7 we obtain an extension and a refinement of Theorem B in the setting of a linear mapping preserving a polyhedral cone. The situation

6

for the nonpolyhedral case is also investigated carefully.

We give some multi-purpose examples in Section 8, and pose some open questions in Section 9, the final section of our paper.

Applications of our theory to solvability of linear equations over cones will be given in a forthcoming paper [T–S 2].

Before we end this section, we would like to point out that in this paper our proofs of theorems on a linear mapping preserving a polyhedral cone rely much on the fact that if A leaves invariant a polyhedral cone K, then K contains generalized eigenvectors of A of all possible orders between 1 and ν, where ν is the index of $\rho(A)$ as an eigenvalue of A. The latter fact follows from [Tam 3, Theorem 7.5(ii)] which asserts that there always exists a vector x in K (a polyhedral cone) such that $(A - \rho(A)I)^{\nu}x = \mathbf{0}$, and $(A - \rho(A)I)^{i}x$ are nonzero vectors of K for $i = 0, \cdots, \nu - 1$. This last fact is, in turn, proved in [Tam 3], using the minimal generating matrix of a polyhedral cone as a tool and depending on the corresponding known result for a nonnegative matrix. However, in our next paper [Tam 4], we shall offer an analytic and cone-theoretic proof of a result stronger than this last fact, without assuming the corresponding result for a nonnegative matrix. Thus, our treatment can be kept independent of the known results on a nonnegative matrix.

2. Preliminaries

We shall restrict our attention to finite-dimensional vector spaces. A familiarity with convex cones, cone-preserving maps, and graph-theoretic properties of nonnegative matrices is assumed. (For references, see [Bar 2], [B–P] or [Schn 3].) The terminology and notation of the previous papers in this sequence are adopted here. For convenience, we collect some of them below, together with some additional new definitions and notation.

Unless specified otherwise, all matrices considered in this paper are square. We always use K to denote a proper (i.e. closed, full, pointed convex) cone of $\mathbb{R}^{n}$, and $\pi(K)$ to denote the set of all $n \times n$ real matrices A that satisfy

$AK \subseteq K$. Elements of $\pi(K)$ are referred to as *cone-preserving maps* (or more commonly as *positive-operators* on K).

If $S \subseteq K$, we denote by $\Phi(S)$ the *face of K generated by S*, that is, the intersection of all faces of K including S. If $x \in K$, we write $\Phi(\{x\})$ simply as $\Phi(x)$. A vector $x \in K$ is called an *extreme vector* if either x is the zero vector or x is nonzero and $\Phi(x) = \{\lambda x : \lambda \geq 0\}$; in the latter case, the face $\Phi(x)$ is called an *extreme ray*. A proper cone K is said to be *polyhedral* if it has finitely many extreme rays.

The set of all faces of K is denoted by $\mathcal{F}(K)$. By a *nontrivial face* of K we mean a face other than K itself or the zero face $\{\mathbf{0}\}$. By the *dual cone K^** of K we mean the proper cone $\{z \in \mathbb{R}^n : \langle z, x \rangle \geq 0 \text{ for all } x \in K\}$, where $\langle z, x \rangle$ is the usual inner product of $\mathbb{R}^n$ between the vectors z and x. We also use d_K to denote the *duality operator of K*, i.e. the mapping from $\mathcal{F}(K)$ to $\mathcal{F}(K^*)$ given by: $d_K(F) = (\operatorname{span} F)^\perp \bigcap K^*$ (see [Tam 2]). A face F of K is said to be *exposed* if there exists a face G of K^* such that $F = d_{K^*}(G)$; or equivalently, if $F = d_{K^*} \circ d_K(F)$. A cone K is called *facially exposed* if each of its faces is exposed; or equivalently, d_K is injective, or d_{K^*} is surjective (see [Tam 2, Proposition 2.5 (a) and Corollary 2.6]).

The set of all $n \times n$ complex matrices is denoted by $\mathcal{M}_n$. The range space, nullspace and the spectral radius of a matrix $A \in \mathcal{M}_n$ are denoted respectively by $\mathcal{R}(A)$, $\mathcal{N}(A)$ and $\rho(A)$. If A is a real matrix, its range space and null space are understood to be taken in the corresponding real spaces. Eigenvalues of A with modulus $\rho(A)$ are said to compose the *peripheral spectrum of A*.

For any $A \in \mathcal{M}_n$ and $b \in \mathbb{C}^n$, by the *cyclic space* (relative to A) *generated by the vector b*, denoted by W_b, we mean the subspace span $\{b, Ab, A^2 b, \cdots\}$. (Again, when A and b are both real, the above linear span is taken in the real space.) If λ is an eigenvalue of A, we denote by $\nu_\lambda(A)$ the index of λ as an eigenvalue of A.

Let A be an $n \times n$ real matrix. It is known that a necessary and sufficient condition for the existence of a proper cone K of $\mathbb{R}^n$ such that $A \in \pi(K)$ is

that, for each eigenvalue λ in the peripheral spectrum of A, we have $\nu_\lambda(A) \leq \nu_{\rho(A)}(A)$. (Then clearly $\rho(A)$ is an eigenvalue of A.) This condition is now referred to as the *Perron-Schaefer condition* (see [Schn 2, the paragraph after Theorem 1.1]).

If $A \in \mathcal{M}_n$ and x is a nonzero vector of $\mathbb{C}^n$ such that $(\lambda I - A)^k x = \mathbf{0}$ for some $\lambda \in \mathbb{C}$ and some positive integer k, then x is called a *generalized eigenvector of A* corresponding to (the eigenvalue) λ. The least such integer k is called the *order of x* as a generalized eigenvector of A, and is denoted by $\mathrm{ord}_A(x)$.

For any $A \in \mathcal{M}_n$ and $x \in \mathbb{C}^n$, we define the *local spectral radius of A at x*, denoted by $\rho_x(A)$, as follows. If x is the zero vector, take $\rho_x(A)$ to be 0. If x is a nonzero vector, write x uniquely as a sum of generalized eigenvectors of A, say,

$$x = x_1 + \cdots + x_k,$$

where $k \geq 1$, and $x_1, \cdots, x_k$ are generalized eigenvectors of A corresponding to distinct eigenvalues $\lambda_1, \cdots, \lambda_k$ respectively. Define $\rho_x(A)$ to be $\max_{1 \leq i \leq k} |\lambda_i|$. For other equivalent definitions, see [T–W, Theorem 2.2].

If $A \in \pi(K)$ and $x \in K$ is an eigenvector (respectively, generalized eigenvector), then x is called a *distinguished eigenvector* (respectively, *distinguished generalized eigenvector*) *of A for K*, and the corresponding eigenvalue is known as a *distinguished eigenvalue of A for K*. When there is no danger of confusion, we simply use the terms distinguished eigenvector, distinguished generalized eigenvector and distinguished eigenvalue (of A). (For reference, see [Tam 3].) By an *extremal distinguished eigenvector* of A corresponding to the (distinguished) eigenvalue λ, we mean a nonzero extreme vector of the cone $\mathcal{N}(\lambda I - A) \bigcap K$.

The nonnegative orthant of $\mathbb{R}^n$ is denoted by $\mathbb{R}^n_+$. It is clear that $\mathbb{R}^n_+$ is a proper cone of $\mathbb{R}^n$, and also that $\pi(\mathbb{R}^n_+)$ is the cone of all $n{\times}n$ nonnegative matrices. When we consider an $n{\times}n$ nonnegative matrix as a cone-preserving map, unless specified otherwise, we always mean that the underlying cone is $\mathbb{R}^n_+$.

A familiarity with the diagraph and classes of a nonnegative matrix is assumed. (For reference, see, for instance, [Schn 3].) If n is a positive integer, we denote by $\langle n \rangle$ the set $\{1, 2, \cdots, n\}$. We always use P to denote an $n \times n$ nonnegative matrix for some positive integer n. The subsets of $\langle n \rangle$ are usually denoted by capital Latin letters I, S, etc., except that we use small Greek letters α, β, etc. to denote the classes of P. The accessibility relation is usually defined between the classes of P, but we also say i *has access to* j (where $i, j \in \langle n \rangle$) if there is a directed path in $G(P)$ (the *digraph of* P) from i to j. Similarly, we also say i has access to a subset of $\langle n \rangle$ with the obvious meaning. If $S, T \subseteq \langle n \rangle$, we denote by P_{ST} the principal submatrix of P with rows indexed by S and columns indexed by T.

Sometimes we say a class α of P is associated with λ. By that we mean $\lambda = \rho(P_{\alpha\alpha})$. A class α is said to be *semi-distinguished* if $\rho(P_{\beta\beta}) \leq \rho(P_{\alpha\alpha})$ for any class β which has access to α but not equal to α. If, in this definition, the weak inequality is replaced by strict inequality of the same type, we recover the usual definition of a distinguished class.

A subset I of $\langle n \rangle$ is called an *initial subset for* P if either I is empty, or I is nonempty and $P_{I'I} = \mathbf{0}$, where $I' = \langle n \rangle \backslash I$; equivalently, for every $j \in \langle n \rangle$, I contains j whenever j has access to I. Clearly an initial subset for P which is also a class of P is simply an initial class in the usual sense. It is also not difficult to see that a nonempty subset I of $\langle n \rangle$ is an initial subset for P if and only if I is the union of an *initial collection of classes* of P, where a nonempty collection of classes of P is said to be initial if whenever it contains a class α, it also contains all classes having access to α. One can readily verify that the intersection and union of two initial subsets for P are both initial subsets for P. Thus the collection of all initial subsets for P forms a sublattice of $2^{\langle n \rangle}$, the lattice of all subsets of $\langle n \rangle$. We denote this sublattice by $\mathcal{I}$.

It is known that $\mathcal{F}(K)$ forms a lattice under inclusion as the partial ordering, with meet and join given by: $F \bigwedge G = F \bigcap G$ and $F \bigvee G = \Phi(F \bigcup G)$. If $A \in \pi(K)$, then a face F of K is said to be A-*invariant* if $AF \subseteq F$. Clearly, the meet of two A-invariant faces is A-invariant. The join of two A-invariant

faces is also A-invariant; this is because, for any two such faces F, G, we have

$$A(F \bigvee G) = A(\Phi(F \bigcup G)) \subseteq \Phi(A(F \bigcup G)) \subseteq \Phi(F \bigcup G) = F \bigvee G.$$

Thus, the set of all A-invariant faces of K, which we denote by $\mathcal{F}_A(K)$ (or simply by $\mathcal{F}_A$ if there is no danger of confusion), forms a sublattice of $\mathcal{F}(K)$. A face F of K is said to be A-*invariant join-reducible* if F is A-invariant and is the join of two (and hence, of all) A-invariant faces of K that are properly included in F; in other words, F is join-reducible in the lattice $\mathcal{F}_A$ in the usual lattice-theoretic sense. (For definitions of lattice-theoretic terms, see [Bir].) An A-invariant face which is not A-invariant join-reducible is said to be A-*invariant join-irreducible*. According to our definition, the zero face is always A-invariant join-irreducible.

For any $F \in \mathcal{F}_A$, we denote by $\rho_F(A)$ (or simply by ρ_F) the spectral radius of the restriction map $A|_{\operatorname{span} F}$; then we also say F is *associated with* ρ_F. A face F is said to be a *distinguished A-invariant face of K* (*associated with* λ) if F is a nonzero A-invariant face of K such that $\rho_G < \rho_F$ for any nonzero A-invariant face G properly included in F (and $\rho_F = \lambda$).

We shall need the following explicit characterization of the smallest A-invariant face that contains a given vector x of K.

Lemma 2.1. *Let $A \in \pi(K)$ and let $x \in K$. Then $\Phi((I + A)^{n-1}x)$ is the smallest A-invariant face of K containing x.*

Proof. For convenience, denote the vector $(I + A)^{n-1}x$ by y. Note that y is a positive linear combination of the vectors $x, Ax, \cdots, A^{n-1}x$ of K and also that these vectors span W_x (the cyclic space generated by x). So y belongs to the relative interior of $W_x \bigcap K$. But clearly $Ay \in W_x \bigcap K$, so there exists some $\alpha > 0$ such that $\alpha y - Ay \in W_x \bigcap K$, and hence $\alpha y \geq^K Ay$. Thus, $\Phi(y)$ is an A-invariant face which, in addition, also contains x, as $y \geq^K x$. If F is an A-invariant face of K that contains x, then F must contain $Ax, \cdots, A^{n-1}x$,

11

and hence also y; thus $F \supseteq \Phi(y)$. This proves that $\Phi(y)$ is the smallest A-invariant face of K that contains x.

$\square$

3. The invariant faces
associated with a nonnegative matrix

It is known that every face of $\mathbb{R}_+^n$ is of the form

$$F_I = \{x \in \mathbb{R}_+^n : \operatorname{supp}(x) \subseteq I\},$$

where $I \subseteq \langle n \rangle$, and $\operatorname{supp}(x)$ is the *support of* x, i.e. the set $\{i \in \langle n \rangle : \xi_i \neq 0\}$ for $x = (\xi_1, \cdots, \xi_n)^T$. Indeed, as can be readily seen, the mapping $I \longmapsto F_I$ is an isomorphism between the lattices $2^{\langle n \rangle}$ and $\mathcal{F}(\mathbb{R}_+^n)$. The following result asserts that if P is an $n \times n$ nonnegative matrix, then under this isomorphism, the initial subsets for P correspond to the P-invariant faces of $\mathbb{R}_+^n$.

Theorem 3.1. *Let P be an $n \times n$ nonnegative matrix. Denote by $\mathcal{I}$ the lattice of all initial subsets for P and by $\mathcal{F}_P$ the lattice of all P-invariant faces of $\mathbb{R}_+^n$. Then the association $I \longmapsto F_I$ induces an isomorphism from the lattice $\mathcal{I}$ onto the lattice $\mathcal{F}_P$.*

Proof. Let $\triangle : \mathcal{I} \longrightarrow \mathcal{F}_P$ be the mapping defined by $\triangle(I) = F_I$. First, we need to show that $\triangle$ is a well-defined mapping. Let $I \in \mathcal{I}$. To show that F_I is P-invariant, take any vector $x \in F_I$. Then

$$
\begin{aligned}
\operatorname{supp}(Px) &= \{j \in \langle n \rangle : p_{ji} \neq 0 \text{ for some } i \in \operatorname{supp}(x)\} \\
&\subseteq \{j \in \langle n \rangle : j \text{ has access to } \operatorname{supp}(x)\} \\
&\subseteq I,
\end{aligned}
$$

where the last inclusion follows from the fact that $\operatorname{supp}(x) \subseteq I$ and I is an initial subset for P. Hence, by definition, we have $Px \in F_I$.

Because $\triangle$ is just a restriction of the isomorphism $I \longmapsto F_I$ between the lattices $2^{\langle n \rangle}$ and $\mathcal{F}(\mathbb{R}_+^n)$, and $\mathcal{I}$ and $\mathcal{F}_P$ are respectively sublattices of $2^{\langle n \rangle}$ and $\mathcal{F}(\mathbb{R}_+^n)$, $\triangle$ is a one-to-one lattice homomorphism. It remains to show that the mapping $\triangle$ is onto.

Let F be a P-invariant face. As a face of $\mathbb{R}_+^n$, F must be of the form F_S for some $S \subseteq \langle n \rangle$; indeed, S is the set $\bigcup_{x \in F} \operatorname{supp}(x)$. Let $i \in S$. Consider

13

any $j \in \langle n \rangle$, which has access to i but not equal to i. Since j has access to i, there exists a positive integer k such that the (j,i) entry of P^k is nonzero; or, in other words, $j \in \mathrm{supp}\,(P^k e_i)$, where e_i is the ith standard unit vector of $\mathbb{R}^n$. But $P^k e_i \in F$, as $e_i \in F$ and F is P-invariant, so $j \in S$. This shows that S is an initial subset for P, and thus establishes the surjectivity of $\triangle$. The proof is complete.

$\square$

Let $\mathcal{K}$ be a nonempty collection of classes of P. A class $\alpha \in \mathcal{K}$ is said to be *final in* $\mathcal{K}$ if it has no access to other classes of $\mathcal{K}$. If I is a nonempty initial subset for P, then as mentioned before, I is the union of all classes in an initial collection $\mathcal{K}$ of classes of P. An initial subset I for P is said to be *determined by a class* α of P if it is the union of all classes of P having access to α (or, in other words, α is the only class final in the initial collection corresponding to I); in this case, we write F_I simply as F_α. The use of the notation F_α here agrees with that of [T–S 1, Section 4]. Since we use only small Greek letters to denote classes, the use of this notation should cause no confusion. According to Theorem 3.1, each F_α is a P-invariant face.

Lemma 3.2. *Let P be an $n \times n$ nonnegative matrix. If α is a distinguished class of P associated with the eigenvalue λ, then F_α contains a unique (up to multiples) eigenvector of P corresponding to λ. Furthermore, this eigenvector belongs to $\mathrm{relint}\, F_\alpha$ and is an extremal distinguished eigenvector of P.*

Proof. First, note that $P|_{\mathrm{span}\, F_\alpha}$ can be represented by the principal submatrix of P with rows and columns indexed by the initial subset for P determined by α. As such, the spectrum of $P|_{\mathrm{span}\, F_\alpha}$ is simply the union of the spectra of all possible submatrices $P_{\beta\beta}$ for which β is a class of P that has access to α. Since α is a distinguished class, it follows that $\rho(P|_{\mathrm{span}\, F_\alpha}) = \rho(P_{\alpha\alpha}) = \lambda$. According to the Perron-Frobenius theorem, there exists an eigenvector x of P corresponding to λ that lies in F_α. If $x \in \mathrm{rbd}\, F_\alpha$, then $\Phi(x)$ is a P-invariant face properly included in F_α, and by Theorem 3.1 there

14

is an initial subset I for P properly included in the initial subset determined by α such that $\Phi(x) = F_I$. But then $\rho_{\Phi(x)} = \rho(P_{II}) < \lambda$, which contradicts our assumption on x. This shows that $x \in \operatorname{relint} F_\alpha$.

If P has an eigenvector in F_α corresponding to λ, which is not a multiple of x, then we readily obtain an eigenvector corresponding to λ that lies in $\operatorname{rbd} F_\alpha$. But as we have just shown, this would lead to a contradiction. This proves the uniqueness of the desired eigenvector x. It also follows that x is an extremal distinguished eigenvector.

$\square$

We now offer a cone-theoretic proof of the following Frobenius-Victory theorem, first named in [T–S 1] (see Theorem 2.1 and the subsequent remarks there).

Theorem 3.3. *Let P be an $n \times n$ nonnegative matrix.*

(i) *For any real number λ, λ is a distinguished eigenvalue of P (for $\mathbb{R}_+^n$) if and only if there exists a distinguished class α of P such that $\rho(P_{\alpha\alpha}) = \lambda$.*

(ii) *If α is a distinguished class of P, then there is a (up to multiples) unique nonnegative eigenvector $x^\alpha = (\xi_1, \cdots, \xi_n)^T$ corresponding to $\rho(P_{\alpha\alpha})$ with the property that $\xi_i > 0$ if and only if i has access to α.*

(iii) *For each distinguished eigenvalue λ of P, the cone $\mathcal{N}(\lambda I - P) \bigcap \mathbb{R}_+^n$ is simplicial and its extreme vectors are precisely all the distinguished eigenvectors of P of the form x^α as given in (ii), where α is a distinguished class such that $\rho(P_{\alpha\alpha}) = \lambda$.*

Proof.

(i): The " if " part follows from Lemma 3.2. To prove the " only if " part, choose a distinguished A-invariant face F of $\mathbb{R}_+^n$ associated with λ. By Theorem 3.1 $F = F_I$ for some nonempty initial subset I for P. Note that there can be only one class final in the initial collection of classes corresponding to I, say α, (i.e. $F_I = F_\alpha$) and also that α is a distinguished class associated with λ; otherwise, it would be possible to choose a nonempty

15

initial subset I' properly included in I, and hence $F_{I'}$ properly included in F_I, such that $\rho_{F_{I'}} = \rho_{F_I} = \lambda$, contradicting the assumption that F is a distinguished A-invariant face.

(ii): Follows from Lemma 3.2 (and the definition of F_α).

(iii): By Lemma 3.2 each distinguished eigenvector of the form x^α, where α is a distinguished class associated with λ, is an extreme vector of $\mathcal{N}(\lambda I - P) \bigcap \mathbb{R}_+^n$. Conversely, if x is an (nonzero) extreme vector of $\mathcal{N}(\lambda I - P) \bigcap \mathbb{R}_+^n$, then as can be readily shown, $\Phi(x)$ is a distinguished A-invariant face of $\mathbb{R}_+^n$. ¿From the proof of the " only if " part of (i), then we have $\Phi(x) = F_\alpha$ for some distinguished class α associated with λ. But by Lemma 3.2 the eigenvector of P corresponding to λ that lies in F_α is unique, so $x = x^\alpha$. This proves that the extreme vectors of the cone $\mathcal{N}(\lambda I - P) \bigcap \mathbb{R}_+^n$ are precisely those of the given form. That the cone $\mathcal{N}(\lambda I - P) \bigcap \mathbb{R}_+^n$ is simplicial, i.e. its set of distinct (up to multiples) extreme vectors is linearly independent, follows from the combinatorial properties of the supports of these vectors.

$\square$

Using the Frobenius-Victory theorem, in [Tam 3, Theorem 5.2] a cone-theoretic proof is offered for the well-known Nonnegative Basis theorem for a nonnegative matrix (or a singular M-matrix). [A stronger result known as the Preferred-Basis theorem has also been found. See [H–S].] Hershkowitz and Schneider [H–S, Section 5] have also extended the Nonnegative Basis theorem to cover the case of a distinguished eigenvalue. We reformulate their result as Theorem 3.4 below and offer an independent proof which is based on the Nonnegative-Basis theorem and makes use of cone-theoretic arguments.

Theorem 3.4. *Let P be an $n \times n$ nonnegative matrix, and let λ be a distinguished eigenvalue of P. Let $\alpha_1, \cdots, \alpha_p$ be all the semi-distinguished classes of P associated with λ. Then the generalized eigenspace of P corresponding to λ contains nonnegative vectors $x^{\alpha_1}, \cdots, x^{\alpha_p}$ such that $x^{\alpha_i} \in$ relint F_{α_i} for each i. Furthermore, any such collection forms a basis for the*

subspace spanned by the nonnegative generalized eigenvectors of P corresponding to λ.

Before we come to the proof of Theorem 3.4, we need the following lemma.

Lemma 3.5. *Let P be an $n \times n$ nonnegative matrix. If F is a P-invariant face of $\mathbb{R}^n_+$ which contains in its relative interior a generalized eigenvector of P, then F must be of the form F_I, where I is a nonempty initial subset for P with the property that each class final in the initial collection of classes corresponding to I is a semi-distinguished class associated with ρ_F.*

Proof. By Theorem 3.1 F is of the form F_I for some initial subset I for P. Denote by B the principal submatrix of P with columns and rows indexed by I. Since P has a generalized eigenvector that lies in relint F, the nonnegative matrix B has a positive generalized eigenvector. Hence, by [Tam 3, Theorem 5.1] $\rho_F (= \rho(B))$ is the only distinguished eigenvalue of B^T (for the corresponding nonnegative orthant). By the Frobenius-Victory theorem it follows that every initial class of B^T, and hence every final class of B, is associated with ρ_F. But the final classes of B are precisely the classes final in the initial collection of classes corresponding to I, hence our assertion follows.

$\square$

Proof of Theorem 3.4. Let α be any semi-distinguished class of P associated with λ. Let Q be the principal submatrix of P with rows and columns indexed by the initial subset determined by α. Then

$$\begin{aligned}\rho(Q) &= \max\{\rho(P_{\beta\beta}) : \beta \text{ has access to } \alpha\} \\ &= \lambda,\end{aligned}$$

where the last equality follows from the assumption that α is a semi-distinguished class of P. An application of the first part of the Nonnegative-Basis theorem (see [Tam 3, Theorem 5.2]) to Q guarantees that there exists a

17

positive generalized eigenvector w of Q corresponding to λ. For convenience, we index the components of w by the initial subset of P determined by α. Let x^α be the vector in $\mathbb{R}_+^n$ defined by: $(x^\alpha)_i$ equals w_i if i has access to α, and equals zero otherwise. Then x^α is the desired generalized eigenvector of P corresponding to λ which is associated with the semi-distinguished class α.

It is clear that any collection of vectors x^α, with one vector for each semi-distinguished class α associated with λ, forms a linearly independent family, in view of the combinatorial properties of these vectors. To complete the proof, it remains to show that if u is a nonnegative generalized eigenvector of P corresponding to λ, then u is spanned by any such collection of vectors x^α. For that purpose, it suffices to show that $\mathrm{supp}\,(u) \subseteq I$, where we use I to denote the union of all classes of P having access to at least one semi-distinguished class associated with λ. This is because, then we can apply the Nonnegative Basis theorem to the principal submatrix of P with rows and columns indexed by I to draw the desired conclusion.

Let u be any nonnegative generalized eigenvector of P corresponding to λ. By Lemma 2.1 the face $\Phi((I + P)^{n-1}u)$ is the smallest P-invariant face of $\mathbb{R}_+^n$ containing u, and by Theorem 3.1 it must be of the form F_S, for a unique initial subset S for P. (In fact, S is the smallest initial subset for P including $\mathrm{supp}\,(u)$, i.e. it is the union of all classes of P having access to $\mathrm{supp}\,(u)$.) Since F_S contains a generalized eigenvector of P corresponding to λ in its relative interior, namely, the vector $(I + P)^{n-1}u$, by Lemma 3.5 each class final in the initial collection of classes corresponding to S is a semi-distinguished class associated with λ. Hence, we have

$$\mathrm{supp}\,(u) \subseteq \mathrm{supp}\,((I + P)^{n-1}u) = S \subseteq I,$$

as desired.

$\square$

The following characterizations of different types of P-invariant faces

associated with a nonnegative matrix P motivate much of our subsequent work in this paper.

Theorem 3.6. *Let P be an $n \times n$ nonnegative matrix. Let I be an initial subset for P. Then*

(i) *F_I is a minimal nonzero P-invariant face if and only if I is an initial class of P.*

(ii) *F_I is a nonzero P-invariant join-irreducible face if and only if I is an initial subset determined by a single class.*

(iii) *F_I is a P-invariant face which contains in its relative interior a generalized eigenvector (respectively, an eigenvector) of P corresponding to λ if and only if I is a nonempty initial subset such that each class final in the initial collection of classes corresponding to I is a semi-distinguished (respectively, distinguished) class associated with λ.*

(iv) *F_I is a P-invariant join-irreducible face which contains in its relative interior a generalized eigenvector (respectively, an eigenvector) of P corresponding to λ if and only if I is an initial subset determined by a semi-distinguished (respectively, distinguished) class associated with λ.*

Proof. As in the proof of Theorem 3.1 we denote by $\triangle$ the isomorphism from $\mathcal{I}$, the lattice of all initial subsets for P, onto $\mathcal{F}_P$, the lattice of all P-invariant faces of $\mathbb{R}^n_+$, given by $\triangle(I) = F_I$.

(i): The minimal nonempty members of $\mathcal{I}$ are precisely those initial subsets of P determined by an initial class. Under the lattice isomorphism $\triangle$, they clearly correspond to the minimal nonzero P-invariant faces of $\mathbb{R}^n_+$.

(ii): Note that the nonempty join-irreducible members of the lattice $\mathcal{I}$ are precisely those initial subsets determined by a single class, whereas the nonzero join-irreducible members of $\mathcal{F}_P$ are the nonzero P-invariant join-irreducible faces. But $\triangle$ sends the empty set to the zero face and as a lattice isomorphism it preserves the join-irreducibility property, so our assertion follows.

(iii): " Only if " part: The " generalized eigenvector " case follows

19

immediately from Lemma 3.5. To prove the " eigenvector " case, we denote by B, as in the proof of Lemma 3.5, the principal submatrix of P with columns and rows indexed by I. Here, instead of using [Tam 3, Theorem 5.1], we apply [Tam 3, Theorem 5.4] to B and deduce that $\nu_{\rho_F}(B) = 1$, and also that I is a nonempty initial subset with the property that each class final in the initial collection of classes corresponding to I is a semi-distinguished class (of B, or equivalently, of P) associated with ρ_F. It remains to show that each class final in the initial collection corresponding to I is, in fact, a distinguished class. (Here, if we apply the Rothblum Index theorem, we can already draw the desired conclusion. But, providing an alternative cone-theoretic proof for the Rothblum Index theorem and its extension is one of the purposes of this paper, so we proceed instead as follows.) Suppose that there is a class, say β, which is final in the initial collection corresponding to I but is not a distinguished class. Then by Theorem 3.4 we can find a nonnegative generalized eigenvector $x = (\xi_i)^T$ of B corresponding to ρ_F with the property that $\xi_i > 0$ if and only if i has access to β. ¿From a consideration of supports of vectors, it is clear that x cannot be written as a linear combination of vectors of the form x^α as given in Theorem 3.3(ii), where α is a distinguished class of B associated with ρ_F. Hence, it follows that x is a generalized eigenvector of order greater than 1. Thus, we obtain $\nu_{\rho_F}(B) \geq 2$, which is a contradiction.

" If " part: We give the proof for the " generalized eigenvector " case, and omit the proof for the " eigenvector " case, which depends on the use of the Frobenius -Victory theorem and is similar and easier. We denote by $\mathcal{K}$ the initial collection of classes of P corresponding to the initial subset I.

Let $\alpha_1, \cdots, \alpha_k$ be the classes final in $\mathcal{K}$. By our assumption on I, each α_i is a semi-distinguished class associated with the eigenvalue λ. By Theorem 3.4, for each i, $1 \leq i \leq k$, there is a generalized eigenvector, say x_i, of P corresponding to λ that lies in relint F_{α_i}. Since I is an initial subset, it follows that the vector $\sum_{i=1}^k x_i$ is a generalized eigenvector of P corresponding to λ that lies in relint F_I.

(iv): The " only if " part and the " if " part follow respectively from the corresponding parts of (ii) and (iii).

$\square$

4. The spectral pair of a face

Let $A \in \pi(K)$. For any face F of K, A-invariant or not, we are going to assign to it an ordered pair of nonnegative real numbers, known as the spectral pair of F relative to A. Such spectral pairs of faces will turn out to be useful in our later investigations. But first we need the concept of a spectral pair of a vector relative to an arbitrary (square) matrix, and for this purpose we introduce the concept of the order of a vector relative to a matrix. We thus extend the usual concept of the order of a generalized eigenvector.

Let $A \in \mathcal{M}_n$ and let x be a nonzero vector of $\mathbb{C}^n$. Consider the (unique) representation of x as a sum of generalized eigenvectors of A, say,

$$x = x_1 + \cdots + x_m,$$

where $x_1, \cdots, x_m$ are generalized eigenvector of A corresponding respectively to distinct eigenvalues $\lambda_1, \cdots, \lambda_m$. By definition, $\rho_x(A)$ equals $\max_{1 \leq i \leq m} |\lambda_i|$. By the *order of x relative to A*, denoted by $\text{ord}_A(x)$, we mean the maximum of the orders of generalized eigenvectors, each corresponding to an eigenvalue of modulus $\rho_x(A)$, that appear in the above representation of x. Now we denote the ordered pair $(\rho_x(A), \text{ord}_A(x))$ by $\text{sp}_A(x)$ and refer to it as the *spectral pair of x relative to A*. We also set $\text{sp}_A(\mathbf{0}) = (0, 0)$ to take care of the zero vector $\mathbf{0}$. We denote by $\preceq$ the lexicographic ordering between ordered pairs of real numbers given by:

$$(\xi_1, \xi_2) \preceq (\eta_1, \eta_2) \text{ if either } \xi_1 < \eta_1, \text{ or } \xi_1 = \eta_1 \text{ and } \xi_2 \leq \eta_2.$$

We also write $(\xi_1, \xi_2) \prec (\eta_1, \eta_2)$, if $(\xi_1, \xi_2) \preceq (\eta_1, \eta_2)$ but the equality does not hold in the usual sense.

Using the definition of the spectral pair of a vector (relative to a matrix), it is easy to establish the following:

21

Remark 4.1. For any $A \in \mathcal{M}_n$, $x, y \in \mathbb{C}^n$, $0 \neq \lambda \in \mathbb{C}$, we have

(i) $\mathrm{sp}_A(\lambda x) = \mathrm{sp}_A(x)$.

(ii) $\mathrm{sp}_A(Ax)$ equals $\mathrm{sp}_A(x)$ if $\rho_x(A) > 0$, and equals $(0, \mathrm{ord}_A(x) - 1)$ if $\rho_x(A) = 0$ and $x \neq \mathbf{0}$.

(iii)$\mathrm{sp}_A(x+y) \preceq \max\{\mathrm{sp}_A(x), \mathrm{sp}_A(y)\}$, where the maximum is taken in the sense of lexicographic ordering.

Part (iii) of Remark 4.1 is a strengthening of the known result [T–W, Lemma 2.3] that if $x_1, x_2 \in \mathbb{C}^n$, then

$$\rho_{x_1+x_2}(A) \leq \max\{\rho_{x_1}(A), \rho_{x_2}(A)\}.$$

Indeed, we have indicated an easy alternative proof.

Here we would like to mention some relevant results which we need later. For any $n \times n$ complex matrix A and any eigenvalue λ of A, let $E_\lambda^{(0)}$ denote the projection of $\mathbb{C}^n$ onto the generalized eigenspace $\mathcal{N}((\lambda I - A)^n)$ along the direct sum of other generalized eigenspaces of A. Also define the components of A by

$$E_\lambda^{(k)} = (A - \lambda I)^k E_\lambda^{(0)}, k = 0, 1, \cdots.$$

In [Schn 2, Theorem 5.2 (iii)] it is proved that if K is a proper cone and $A \in \pi(K)$, then $E_\rho^{(\nu-1)}\big|_{\mathbb{R}^n} \in \pi(K)$, where $\rho = \rho(A)$ and $\nu = \nu_{\rho(A)}(A)$. Furthermore, we have, rank $E_\rho^{(\nu-1)} = \mu_\rho(A)$, where $\mu_\rho(A)$ is the exponent of $\rho(A)$, i.e. the number of Jordan blocks of A of maximal order corresponding to $\rho(A)$. (This latter fact is always true; it does not depend on the condition that $A \in \pi(K)$.) Thus, $E_\rho^{(\nu-1)} K$ is a cone of dimension $\mu_\rho(A)$ which consists of some of the distinguished eigenvectors of A corresponding to $\rho(A)$, together with the zero vector. For the purpose of later references, we make a note of the following.

Remark 4.2. If $A \in \pi(K)$, then there exist $\mu_\rho(A)$ (the exponent of $\rho(A)$) linearly independent distinguished eigenvectors of A corresponding to $\rho(A)$, such that each is associated with a maximal Jordan block, in the sense that

each is a vector of the form $(A - \rho(A)I)^{\nu-1}z$ for some generalized eigenvector z of order $\nu = \nu_{\rho(A)}(A)$ corresponding to $\rho(A)$.

Now we make an important observation.

Lemma 4.3. *Let* $A \in \pi(K)$. *For any* $x \in \text{int } K$, *we have*

$$\text{sp}_A(x) = (\rho(A), \nu_{\rho(A)}(A)).$$

Proof. As we have mentioned above, $E_\rho^{(\nu-1)}\big|_{\mathbb{R}^n}$ is nonzero and belongs to $\pi(K)$, where $\nu = \nu_{\rho(A)}(A)$. For any $x \in \text{int } K$, necessarily $E_\rho^{(\nu-1)}x \neq \mathbf{0}$; otherwise, $E_\rho^{(\nu-1)}\big|_{\mathbb{R}^n}$, and hence $E_\rho^{(\nu-1)}$, is the zero operator. Hence, by definition of $E_\rho^{(\nu-1)}$, in the representation of x as a sum of generalized eigenvectors of A, there must be a term which is a generalized eigenvector of A corresponding to $\rho(A)$ and furthermore the order of this generalized eigenvector must be ν. Moreover, by the Perron-Schaefer condition for A, ν is equal to the maximum of the orders of generalized eigenvectors, each corresponding to an eigenvalue belonging to the peripheral spectrum of A, that appear in the representation of x. Therefore, we have

$$\text{sp}_A(x) = (\rho(A), \nu).$$

$\square$

An application of Lemma 4.3 to the restriction of A ($\in \pi(K)$) to the linear span of an A-invariant face F yields immediately the following.

Theorem 4.4. *Let* $A \in \pi(K)$, *and let* F *be an* A-*invariant face of* K. *Then for any vector* $x \in \text{relint } F$, *we have* $\text{sp}_A(x) = (\rho_F, \nu_{\rho_F}(A|_{\text{span } F}))$.

By Theorem 4.4 and the definition of the spectral pair of a vector, we have the following.

Corollary 4.5. *Let* $A \in \pi(K)$. *If* F *is an* A-*invariant face of* K, *then* $\rho_x(A) = \rho_F$ *for any* $x \in \text{relint } F$.

23

The result of Theorem 4.4 also says that, for any A-invariant face F, the value of the spectral pair $\mathrm{sp}_A(x)$ is independent of the choice of x from $\mathrm{relint}\, F$. Now we are going to show that the same is also true for any face F of K.

Theorem 4.6. *Let $A \in \pi(K)$, and let F be a face of K. For any $x \in \mathrm{relint}\, F$, we have*

$$\mathrm{sp}_A(x) = (\rho_{\widehat{F}}, \nu_{\rho_{\widehat{F}}}(A|_{\mathrm{span}\,\widehat{F}})),$$

where $\widehat{F}$ is the smallest A-invariant face of K including F.

Proof. Choose any positive real number α for which $-\alpha$ is not an eigenvalue of A. Consider any vector x chosen from $\mathrm{relint}\, F$. For convenience, denote the vector $(\alpha I + A)^{n-1}x$ by $\widehat{x}$. Then the proof of Lemma 2.1 also shows that $\Phi(\widehat{x})$ equals $\widehat{F}$. Let

$$(1) \qquad\qquad\qquad x = x_1 + \cdots + x_m$$

where $x_1, \cdots, x_m$ are generalized eigenvectors of A corresponding to distinct eigenvalues $\lambda_1, \cdots, \lambda_m$ respectively. Applying $(\alpha I + A)^{n-1}$ to both sides of (1), we obtain

$$(2) \qquad\qquad \widehat{x} = (\alpha I + A)^{n-1}x_1 + \cdots + (\alpha I + A)^{n-1}x_m.$$

By our choice of α, $(\alpha I + A)^{n-1}$ is nonsingular; hence, each $(\alpha I + A)^{n-1}x_i$ is a generalized eigenvector of A corresponding to λ_i, and is of the same order as that of x_i. ¿From the definition of the spectral pair of a vector, now it is clear that we have

$$\mathrm{sp}_A(x) = \mathrm{sp}_A(\widehat{x}) = (\rho_{\widehat{F}}, \nu_{\rho_{\widehat{F}}}(A|_{\mathrm{span}\,\widehat{F}})),$$

where the last equality follows from Theorem 4.4.

$\square$

24

By Theorem 4.6, for any face F of K, the value of the spectral pair $\mathrm{sp}_A(x)$ is independent of the choice of x from relint F. Henceforth, we shall denote this constant value by $\mathrm{sp}_A(F)$, and refer to it as the *spectral pair of F relative to A*. The spectral pair of a face will prove to be a useful concept, though it is not an extension of an existing concept for nonnegative matrices. This probably is due to the fact that its definition implicitly involves the Perron-Schaefer condition, a characterizing property of a cone-preserving map.

In passing, we also take note of the following by-product.

Theorem 4.7. *Let $A \in \pi(K)$. If $\mathbf{0} \neq x \in K$, then there is always a generalized eigenvector y of A corresponding to $\rho_x(A)$ that appears as a term in the representation of x as a sum of generalized eigenvectors of A. Furthermore, we have $\mathrm{ord}_A(x) = \mathrm{ord}_A(y)$.*

Proof. If the face $\Phi(x)$ is A-invariant, our assertion follows from the proof of Lemma 4.3. In view of the proof of Theorem 4.6, our assertion also holds for the case when $\Phi(x)$ is not A-invariant.

$\square$

The following result should also be clear.

Corollary 4.8. *Let $A \in \pi(K)$, and let $\mathbf{0} \neq x \in K$. Denote $\mathrm{ord}_A(x)$ by m. Then $(A - \rho_x(A)I)^{m-1} E^{(0)}_{\rho_x(A)} x$ is a distinguished eigenvector of A corresponding to $\rho_x(A)$.*

In the next result we collect together fundamental properties of spectral pairs of faces (or, of vectors in the cone K).

Theorem 4.9. *Let $A \in \pi(K)$.*
  (i) *For any faces F, G of K, we have*
  (a) $\mathrm{sp}_A(F) = \mathrm{sp}_A(\widehat{F})$, *where $\widehat{F}$ is the smallest A-invariant face of K including F.*
  (b) *If $F \subseteq G$, then $\mathrm{sp}_A(F) \preceq \mathrm{sp}_A(G)$.*

(c) $\mathrm{sp}_A(F \vee G) = \max\{\mathrm{sp}_A(F), \mathrm{sp}_A(G)\}$, *where the maximum is taken in the sense of lexicographic ordering.*

(ii) *For any vectors* $x, y \in K$, *we have*

(a) $\mathrm{sp}_A(x) = \mathrm{sp}_A((I + A)^{n-1}x).$

(b) *If* $x \in \Phi(y)$, *then* $\mathrm{sp}_A(x) \preceq \mathrm{sp}_A(y).$

(c) $\mathrm{sp}_A(x + y) = \max\{\mathrm{sp}_A(x), \mathrm{sp}_A(y)\}$, *where the maximum is taken in the sense of lexicographic ordering.*

Proof. As can be readily shown, properties (a), (b) or (c) of part (i) are each equivalent to the corresponding properties of part (ii). So, for each property, (a), (b) or (c), we need only consider either the one in (i) or the one in (ii).

In view of Theorems 4.4 and 4.6 and the definition of the spectral pair of a face, we have $\mathrm{sp}_A(F) = \mathrm{sp}_A(\widehat{F})$. So we need not consider property (a) further.

Let F, G be faces of K such that $F \subseteq G$. Then clearly we have $\widehat{F} \subseteq \widehat{G}$; thus, $\rho_{\widehat{F}} \leq \rho_{\widehat{G}}$, and if $\rho_{\widehat{F}} = \rho_{\widehat{G}}$ then $\nu_{\rho_{\widehat{F}}}(A|_{\mathrm{span}\,\widehat{F}}) \leq \nu_{\rho_{\widehat{G}}}(A|_{\mathrm{span}\,\widehat{G}})$. That is, we have, $\mathrm{sp}_A(\widehat{F}) \preceq \mathrm{sp}_A(\widehat{G})$, and in view of property (a) of (i), property (b) of (i) follows.

To prove property (c) of (ii), first note that according to Remark 4.1(iii), we always have

$$\mathrm{sp}_A(x + y) \preceq \max\{\mathrm{sp}_A(x), \mathrm{sp}_A(y)\}.$$

Since $x \in \Phi(x + y)$, by property (b) of (ii), $\mathrm{sp}_A(x) \preceq \mathrm{sp}_A(x + y)$. Similarly, we also have, $\mathrm{sp}_A(y) \preceq \mathrm{sp}_A(x + y)$, and hence

$$\max\{\mathrm{sp}_A(x), \mathrm{sp}_A(y)\} \preceq \mathrm{sp}_A(x + y).$$

Therefore, the desired equality holds.

$\square$

An immediate consequence of property (c) of Theorem 4.9 (i) is that, if F is an A-invariant face that satisfies $\mathrm{sp}_A(F) \succ \mathrm{sp}_A(G)$ for all A-invariant faces G properly included in F, then F is A-invariant join-irreducible. The

26

converse of this result is not true. For instance, take A to be the nonnegative matrix $\begin{pmatrix} 1 & 1 \\ 0 & 0 \end{pmatrix}$. Then $\mathbb{R}_+^2$ and $\Phi(e_1)$ are the only nonzero A-invariant faces of $\mathbb{R}_+^2$, so that $\mathbb{R}_+^2$ is an A-invariant join-irreducible face of itself. However, we have $\mathrm{sp}_A(\mathbb{R}_+^2) = (1,1) = \mathrm{sp}_A(\Phi(e_1))$.

By Remark 4.1(i), (ii) and properties (b), (c) of Theorem 4.9(ii), we also readily obtain the following.

Corollary 4.10. *Let $A \in \pi(K)$. For any nonnegative real number λ and any positive integer k, the set*

$$F_{\lambda,k} = \{x \in K : \mathrm{sp}_A(x) \preceq (\lambda, k)\}$$

is an A-invariant face of K. Furthermore, for any nonnegative real numbers λ_1, λ_2, and positive integers k_1, k_2, if $(\lambda_1, k_1) \preceq (\lambda_2, k_2)$, then $F_{\lambda_1,k_1} \subseteq F_{\lambda_2,k_2}$.

For a similar reason, for any positive real number λ, the set

$$F_\lambda = \{x \in K : \rho_x(A) < \lambda\}$$

is an A-invariant face of K; the greater λ is, the larger is the face F_λ. In the case of a positive linear operator T defined on a real Banach lattice E, Meyer-Nieberg (see [MN 1] or [MN 2, pp. 293]) has discovered a class of T-invariant ideals J_λ, which is precisely the linear span of our F_λ when the underlying Banach lattice is $\mathbb{R}^n$ (with positive cone $\mathbb{R}_+^n$). We are going to explain.

For each real number $\lambda > 0$, the ideal J_λ introduced by Meyer-Nieberg is given by:

$$J_\lambda = \{x \in E : \text{the series } \textstyle\sum_{j=0}^\infty T^j |x| / \lambda^{j+1} \text{ is convergent}\}.$$

Here we follow the standard notation of Banach lattice theory (for reference, see [Scha]) and use $|x|$ to denote the modulus of x. First, we show that

$$F_\lambda = \{x \in \mathbb{R}_+^n : \text{the series } \textstyle\sum_{j=0}^\infty T^j x / \lambda^{j+1} \text{ is convergent}\}.$$

If $x \in F_\lambda$, then by definition, $\rho_x(T) < \lambda$. But $\rho_x(T) = \rho(T|_{W_x})$ (see [T–W, Theorem 2.2]), where W_x is the cyclic space generated by x, so $(\lambda I - T|_{W_x})^{-1}$ exists and is given by:

$$(\lambda I - T|_{W_x})^{-1} = \lambda^{-1} \sum_{j=0}^{\infty} (T|_{W_x}/\lambda)^j.$$

Hence, the series $\sum_{j=0}^{\infty} T^j x/\lambda^{j+1} = \sum_{j=0}^{\infty} (T|_{W_x})^j x/\lambda^{j+1}$ is convergent. Conversely, if the series $\sum_{j=0}^{\infty} T^j x/\lambda^{j+1}$ converges, then

$$\lim_{m\to\infty} (T/\lambda)^m (T^i x) = \mathbf{0} \quad \text{for} \quad i = 0, 1, 2, \cdots,$$

and hence

$$\lim_{m\to\infty} (T/\lambda)^m y = \mathbf{0} \quad \text{for every} \quad y \in W_x.$$

It follows that $\lim_{m\to\infty} (T|_{W_x}/\lambda)^m = \mathbf{0}$, and so $\rho_x(T) < \lambda$. This establishes our claim on the set F_λ.

For any $x \in \mathbb{R}^n$, denote the positive part and the negative part of x respectively by x^+ and x^-. Let $x \in \operatorname{span} F_\lambda$. Since F_λ is a face of $\mathbb{R}^n_+$, it is clear that x^+ and x^- both belong to F_λ. Hence, both of the series $\sum_{j=0}^{\infty} T^j x^+/\lambda^{j+1}$ and $\sum_{j=0}^{\infty} T^j x^-/\lambda^{j+1}$ converge, and so does the series $\sum_{j=0}^{\infty} T^j |x|/\lambda^{j+1}$, as $|x| = x^+ + x^-$. This proves the inclusion $\operatorname{span} F_\lambda \subseteq J_\lambda$. Conversely, if $x \in J_\lambda$, then it is clear that both of the series $\sum_{j=0}^{\infty} T^j x^+/\lambda^{j+1}$ and $\sum_{j=0}^{\infty} T^j x^-/\lambda^{j+1}$ converge; hence, $x^+, x^- \in F_\lambda$, and so $x = x^+ - x^- \in \operatorname{span} F_\lambda$. This proves the reversed inclusion and hence the desired equality.

So, in a sense, our Corollary 4.10 is an extension and also a refinement of the above-mentioned result of Meyer-Nieberg for the finite-dimensional case.

Each property about spectral pairs given in Theorem 4.9 clearly implies a corresponding property about (local) spectral radii. For instance, by property (c) of (i) we have the following: *If F, G are A-invariant faces of K, then $\rho_{F \bigvee G} = \max\{\rho_F, \rho_G\}$.* We leave it to the reader to formulate the details.

Now we give equivalent conditions for an A-invariant face of K to be distinguished.

28

Theorem 4.11. *Let $A \in \pi(K)$, and let F be a face of K. The following conditions are equivalent:*

(a) F is a distinguished A-invariant face of K.

(b) F is an A-invariant face, there is a unique (up to positive multiples) eigenvector of A in F that corresponds to ρ_F, and this eigenvector lies in relint F.

(c) $F = \Phi(x)$ for some extremal distinguished eigenvector of A.

(d) F is an A-invariant join-irreducible face of K, which contains in its relative interior an eigenvector of A.

Proof.

(a) $\implies$ (b): Let x be an eigenvector of A corresponding to ρ_F that lies in F. If $x \notin$ relint F, then $\Phi(x)$ is a nonzero A-invariant face properly included in F such that $\rho_{\Phi(x)} = \rho_F$. This contradicts the assumption that F is a distinguished A-invariant face. If $x \in$ relint F and there is an eigenvector, not a multiple of x, corresponding to ρ_F that lies in F, then we readily obtain an eigenvector corresponding to ρ_F that lies in rbd F, and by the first part of our argument we also obtain a contradiction.

The equivalence of (b) and (c) is clear.

(b) $\implies$ (a): Suppose that there is a nonzero A-invariant face G properly included in F such that $\rho_G = \rho_F$. Then there exists an eigenvector of A corresponding to ρ_F that lies in rbd F. This contradicts (b).

(a) $\implies$ (d): By condition (b), which is already proved to be equivalent to condition (a), A has an eigenvector that lies in relint F. Let F_1, F_2 be A-invariant faces such that $F = F_1 \vee F_2$. Then $\rho_F = \max\{\rho_{F_1}, \rho_{F_2}\} = \rho_{F_1}$, say. Since F is distinguished A-invariant, it follows that $F_1 = F$. This proves the A-invariant join-irreducibility of F.

(d) $\implies$ (c): By condition (d) A has an eigenvector x that lies in relint F (and corresponds to ρ_F). Assume to the contrary that x is not an extremal distinguished eigenvector. Then there exist eigenvectors x_1, x_2 of A corresponding to ρ_F such that both vectors belong to rbd F and $x_1 + x_2 = x$.

Then $\Phi(x_1)$ and $\Phi(x_2)$ are both A-invariant faces of K properly included in F such that $\Phi(x_1) \bigvee \Phi(x_2) = \Phi(x_1 + x_2) = F$. This contradicts the assumption that F is A-invariant join-irreducible.

$\square$

By Theorem 3.6(iv), if P is a nonnegative matrix and I is an initial subset for P, then I is determined by a semi-distinguished (respectively, distinguished) class if and only if F_I is a P-invariant join-irreducible face which contains in its relative interior a generalized eigenvector (respectively, an eigenvector) of P. And in view of the equivalent condition (d) of Theorem 4.11 for a distinguished A-invariant face, given any $A \in \pi(K)$, we shall call a face F of K a *semi-distinguished A-invariant face* (associated with λ) if F is an A-invariant join-irreducible face which contains in its relative interior a generalized eigenvector of A (corresponding to λ). Clearly a distinguished A-invariant face is semi-distinguished A-invariant.

Note that we define a nonzero A-invariant face F to be distinguished by the property that $\rho_G < \rho_F$ for any nonzero A-invariant face G properly included in F. Here a semi-distinguished A-invariant face is not defined to be one that satisfies the weaker property obtained by replacing the strict inequality by the weak inequality of the same type, because this latter property is always satisfied! Another reasonable defining property for a semi-distinguished A-invariant face is the following:

F is nonzero A-invariant, and $\mathrm{sp}_A(G) \prec \mathrm{sp}_A(F)$ for any A-invariant face G properly included in F.

In view of Theorem 3.6, it is easy to see that in the case when A is a nonnegative matrix, the preceding property is also another equivalent condition for F to be a semi-distinguished A-invariant face. Indeed, as we shall see, the same is also true whenever the underlying cone K has the property that the dual cone of each of its faces is facially exposed (which is the case if K is polyhedral), but is not so for a general proper cone K.

We shall need the following general result, which is a consequence of the existence of a Jordan basis for a matrix.

Remark 4.12. Let $A \in \mathcal{M}_n$ be such that $\rho(A)$ is an eigenvalue. If z is an eigenvector of A^T corresponding to $\rho(A)$ which is associated with a maximal Jordan block, then z is orthogonal to every vector x for which $\mathrm{sp}_A(x) \prec (\rho(A), \nu_{\rho(A)}(A))$.

In the nonnegative matrix case it is easy to determine whether a face of the nonnegative orthant is semi-distinguished invariant or what the spectral pair of a face (or of a nonnegative vector) is, if we apply Theorems 3.1, 3.6, the Rothblum Index theorem
, and the basic results on spectral pairs of faces (or vectors) obtained in this section. We illustrate this by the following example:

Example 4.13 Consider the following 9×9 nonnegative matrix

$$
P = \begin{bmatrix}
1 & 0 & 8 & 0 & 0 & 8 & 0 & 0 & 0 \\
0 & 3 & 6 & 7 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 2 & 0 & 1 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 3 & 3 & 0 & 4 & 0 & 0 \\
0 & 0 & 0 & 0 & 3 & 5 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 3 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 2 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 3 & 3 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1
\end{bmatrix} .
$$

The matrix P has appeared in [Rot]. The reader may refer to [Rot] for a diagram of $G(P)$ or draw one of his/her own. Obviously each class of P is a singleton. This is done for simplicity only. As can be readily seen, $I = \{1, 2, 3, 4, 5\}$ is an initial subset of $<9>$ determined by the basic class (and hence a semi-distinguished class) $\{5\}$ of P. Let $e_1, \ldots, e_9$ denote the standard unit vectors of $\mathbb{R}^9$. By Theorem 3.6(iv) $F_I = \Phi(e_1 + e_2 + e_3 + e_4 + e_5)$ is a semi-distinguished P-invariant face. That F_I contains in its relative

31

interior a generalized eigenvector (corresponding to $\rho(P) = 3$) is guaranteed by Theorem 3.4, the Nonnegative-Basis theorem; indeed, the vector $4e_1 + e_2 + e_3 + e_4 + e_5$ is a generalized eigenvector of P of order thre
e that lies in relint F_I.

Now we determine the spectral pair of the vector $e_3 + e_6$ relative to P. We do it by applying Theorem 4.6. Note that by Theorem 3.1 the smallest P-invariant face including $\Phi(e_3 + e_6)$ is $\Phi(e_1 + \cdots + e_6)$, as $<6>$ is the smallest initial subset of $<9>$ that includes the subset $\{3, 6\}$. Clearly, the principal submatrix of P with rows and columns indexed by $<6>$, and hence also the restriction of P to span $\{e_1, \ldots, e_6\}$, has spectral radius three and by the Rothblum Index theorem its index is four. By Theorem 4.4 and the definition of the spectral pair of a face, the spectral pair of $\Phi(e_1 + \cdots + e_6)$ is (3,4). Hence, by Theorem 4.6 the spectral pair of the vector $e_3 + e_6$ is also (3,4). A few moments thought should convince the reader that if we determine the spectral pair of $e_3 + e_6$ according to the definition, the process would be rather complicated.

5. AN EXTENSION
OF THE ROTHBLUM INDEX THEOREM

Hershkowitz and Schneider (see [H–S, the paragraph following Theorem 5.10]) proved that the famous Rothblum Index theorem (i.e. Theorem A of Section 1) can be extended to cover the case of a distinguished eigenvalue λ, provided that " basic classes " are replaced by " semi-distinguished classes associated with λ " and ν is replaced by m_λ, the maximal order of distinguished generalized eigenvectors of P corresponding to λ. This is indeed an extension, because for a nonnegative matrix P, as an outcome of the Nonnegative Basis theorem, we have $m_{\rho(P)} = \nu_{\rho(P)}(P)$.

In the case of a linear mapping preserving a polyhedral cone, we have the following extension of the Rothblum Index theorem.

Theorem 5.1. *Let K be a polyhedral cone, and let $A \in \pi(K)$. Let λ be*

a distinguished eigenvalue of A for K. Denote by m_λ the maximal order of distinguished generalized eigenvectors of A corresponding to λ. Then there is a chain of m_λ distinct semi-distinguished A-invariant faces of K associated with λ, but there is no such chain with more than m_λ members.

As can be readily seen, the proof of Theorem 5.1 should consist of two parts: to construct the desired chain of semi-distinguished A-invariant faces, and to establish the maximality of its cardinality. The proof of the maximality of cardinality depends on the following result which has interest of its own.

Lemma 5.2. *Let K be a polyhedral cone, and let $A \in \pi(K)$. If K is a semi-distinguished A-invariant face of itself, then $\mathrm{sp}_A(K) \succ \mathrm{sp}_A(F)$ for any A-invariant face F properly included in K.*

Proof. Since $\mathrm{int}\, K$ contains a generalized eigenvector of A, by [Tam 3, Theorem 5.1] $\rho(A)$ is the only distinguished eigenvalue of A^T for K^*.

We contend that the cone $\mathcal{N}(\rho(A)I - A^T) \bigcap K^*$ is of dimension one. Suppose not. Choose distinct extreme vectors z_1, z_2 from this cone. If $\Phi(z_1) \bigwedge \Phi(z_2) \neq \{\mathbf{0}\}$, then being a nonzero A^T-invariant face $\Phi(z_1) \bigwedge \Phi(z_2)$ would contain an eigenvector of A^T, which necessarily corresponds to $\rho(A)$, and hence is a multiple of z_1, and also of z_2, which is a contradiction. Hence, we have $\Phi(z_1) \bigwedge \Phi(z_2) = \{\mathbf{0}\}$. By our hypothesis, K^* is polyhedral. So each face of K^* is exposed and we can write $\Phi(z_i)$ $(i = 1, 2)$ as $d_K \circ d_{K^*}(\Phi(z_i))$. Thus we have

$$
\begin{aligned}
0 &= \Phi(z_1) \bigwedge \Phi(z_2) \\
&= d_K \circ d_{K^*}(\Phi(z_1)) \bigwedge d_K \circ d_{K^*}(\Phi(z_2)) \\
&= d_K \left(d_{K^*}(\Phi(z_1)) \bigvee d_{K^*}(\Phi(z_2)) \right),
\end{aligned}
$$

which implies that K is the join of the nontrivial A-invariant faces $d_{K^*}(\Phi(z_1))$ and $d_{K^*}(\Phi(z_2))$. So again we arrive at a contradiction. This establishes our

33

contention. And since $\rho(A)$ is the only distinguished eigenvalue of A^T, A^T has (up to multiples) a unique distinguished eigenvector.

In view of Remark 4.2, another consequence of our contention is that, A^T has precisely one maximal Jordan block corresponding to $\rho(A)$. Furthermore, the unique distinguished eigenvector, say w, of A^T for K^* must correspond to this maximal block. Thus, we have

$$(\operatorname{span}\{w\})^{\perp} = \bigoplus_{\lambda \in \sigma(A) \setminus \{\rho(A)\}} \mathcal{N}((\lambda I - A)^n) \oplus U,$$

where U is the space of generalized eigenvectors of A corresponding to $\rho(A)$ of order less than or equal to $\nu_{\rho(A)}(A) - 1$, together with the zero vector.

Now let F be a proper nonzero A-invariant face of K. Since the A^T-invariant face $d_K(F)$ of K^* must contain w, we have $\operatorname{span} F \subseteq (\operatorname{span}\{w\})^{\perp}$. In view of the above direct decomposition for $(\operatorname{span}\{w\})^{\perp}$, it follows that if $\operatorname{span} F$ contains a generalized eigenvector of A corresponding to $\rho(A)$, then the order of such generalized eigenvector must be less than or equal to $\nu_{\rho(A)}(A) - 1$. So we have

$$\operatorname{sp}_A(F) \preceq (\rho(A), \nu_{\rho(A)}(A) - 1) \prec \operatorname{sp}_A(K).$$

$\square$

Proof of Theorem 5.1. By definition of m_λ there exists a distinguished generalized eigenvector x of A corresponding to λ of order m_λ. Clearly the vector $y = (I + A)^{n-1} x$ is also a distinguished generalized eigenvector corresponding to λ of order m_λ, and by Lemma 2.1 $\Phi(y)$ is an A-invariant face. Thus, it is possible to find an A-invariant face of K that contains in its relative interior a generalized eigenvector of A corresponding to λ of order m_λ. Choose F_{m_λ} to be an A-invariant face of K minimal with respect to this property. By definition, clearly we have $\operatorname{sp}_A(F_{m_\lambda}) = (\lambda, m_\lambda)$. We contend that F_{m_λ} is A-invariant join-irreducible, and hence is semi-distinguished. Suppose not. Then we can find A-invariant faces G_1, G_2 properly included in F_{m_λ} such that $F_{m_\lambda} = G_1 \bigvee G_2$. By property (c) of Theorem 4.9(i), either

$\mathrm{sp}_A(G_1)$ or $\mathrm{sp}_A(G_2)$ is equal to $\mathrm{sp}_A(F_{m_\lambda})$, say, $\mathrm{sp}_A(G_1)$. Then by definition of the spectral pair of a face and by Theorem 4.4, $\rho_{G_1} = \lambda$ and $\nu_\lambda(A|_{\mathrm{span}\,G_1}) = m_\lambda$. Since G_1 is polyhedral, according to [Tam 3, Theorem 7.5(ii)], we can find in G_1 a generalized eigenvector u of A corresponding to λ of order m_λ such that $(A - \lambda I)^i u \in G_1$ for $i = 1, \cdots, m_\lambda - 1$. Thus, $\Phi((I + A)^{n-1}u)$ is an A-invariant face included in G_1, and hence properly included in F_{m_λ}, with the property that it contains in its relative interior a generalized eigenvector of A corresponding to λ of order m_λ. This contradicts the minimality of F_{m_λ}, and hence proves our contention for F_{m_λ}.

Next, in view of the polyhedrality of the cone F_{m_λ}, by [Tam 3, Theorem 7.5(ii)] again, we can find in F_{m_λ} a generalized eigenvector of A corresponding to λ

of order $m_\lambda - 1$. Then we can repeat the above argument to obtain a semi-distinguished A-invariant face $F_{m_\lambda - 1}$ of F_{m_λ} such that $\mathrm{sp}_A(F_{m_\lambda - 1}) = (\lambda, m_\lambda - 1)$. Continuing in this way, after a finite number of steps, we eventually arrive at our desired chain of A-invariant faces.

To show that our chain of A-invariant faces is of maximum cardinality, let $H_1 \subseteq \cdots \subseteq H_p$ be an arbitrary chain of distinct semi-distinguished A-invariant faces associated with λ. Then for each i, $1 \leq i \leq p$, $\rho_{H_i} = \lambda$. In view of Lemma 5.2 and the definition of m_λ, it follows that we have

$$(\lambda, 1) \preceq \mathrm{sp}_A(H_1) \prec \mathrm{sp}_A(H_2) \prec \cdots \prec \mathrm{sp}_A(H_p) \preceq (\lambda, m_\lambda).$$

Hence, $p \leq m_\lambda$. This shows that the chain of A-invariant faces (with the desired property) we have constructed is of maximum cardinality.

$\square$

When K is a nonpolyhedral cone, the maximum cardinality of a chain of semi-distinguished A-invariant faces of K associated with a distinguished eigenvalue λ can be less than, equal to, or greater than m_λ, where m_λ has the same meaning as before. The following examples will serve to illustrate this point and also other related points.

Example 5.3. Let α be a given real number with $0 < \alpha < 1$. Let C be the closed convex set in $\mathbb{R}^2$ with extreme points $(k, \alpha^{k-1})^T$, $k = 1, 2, \cdots$, and with recession cone $\mathbf{0}^+ C = \{\lambda(1, 0)^T : \lambda \geq 0\}$. Let K be the proper cone of $\mathbb{R}^3$ given by:

$$K = \{\lambda \begin{pmatrix} x \\ 1 \end{pmatrix} \in \mathbb{R}^3 : x \in C, \lambda \geq 0\} \cup \{\lambda(1, 0, 0)^T : \lambda \geq 0\}.$$

Let

$$A = \begin{bmatrix} 1 & 0 & 1 \\ 0 & \alpha & 0 \\ 0 & 0 & 1 \end{bmatrix}.$$

(The cone K and the matrix A have been considered in [T–W, Example 3.7].) Straightforward calculations show that we have $A(k, \alpha^{k-1}, 1)^T = (k + 1, \alpha^k, 1)^T$ for $k = 1, 2, \cdots$, and $A(1, 0, 0)^T = (1, 0, 0)^T$. It follows that $A \in \pi(K)$. Clearly $\rho(A) = 1$ and $\nu_{\rho(A)}(A) = 2$. It is also not difficult to see that A has only two nonzero A-invariant faces, namely, K and F, where $F = \Phi((1, 0, 0)^T)$, both of which are A-invariant join-irreducible, but only $\Phi((1, 0, 0)^T)$ is semi-distinguished A-invariant. In this case, we have $m_{\rho(A)} = 1 < 2 = \nu_{\rho(A)}(A)$. Here are two other observations we can make of this example (for the nonpolyhedral case):

(i) There does not exist a semi-distinguished A-invariant face G of K such that $\mathrm{sp}_A(G) = \mathrm{sp}_A(K)$. Indeed, F is the only semi-distinguished A-invariant face of K, and we have $\mathrm{sp}_A(F) = (1, 1) \prec (1, 2) = \mathrm{sp}_A(K)$.

(ii) K is not a semi-distinguished A-invariant face of itself, though it has the property that $\mathrm{sp}_A(K) \succ \mathrm{sp}_A(G)$ for all A-invariant faces G properly included in K.

Example 5.4. Let C be the closed convex set in $\mathbb{R}^2$ with recession cone $\mathbf{0}^+ C = \{\lambda(1, 0)^T : \lambda \geq 0\}$, and with extreme points $(k(k - 1)/2, k)^T$, $k = 0, 1, 2, \cdots$. Let K be the proper cone of $\mathbb{R}^3$ given by:

$$K = \{\lambda \begin{pmatrix} x \\ 1 \end{pmatrix} \in \mathbb{R}^3 : x \in C, \lambda \geq 0\} \cup \{\begin{pmatrix} x \\ 0 \end{pmatrix} \in \mathbb{R}^3 : x \in \mathbf{0}^+ C\}.$$

Let $A = J_3(1)$, the 3×3 (upper triangular) elementary Jordan matrix corresponding to the eigenvalue 1. (The matrix A and the cone K have been considered in [Tam 3, Example 5.5]). It is straightforward to check that $A(1,0,0)^T = (1,0,0)^T$, and $A((k(k-1)/2, k, 1)^T) = (k(k+1)/2, k+1, 1)^T$ for $k = 0, 1, 2, \cdots$. It follows that $A \in \pi(K)$. Clearly, A has only two nonzero A-invariant faces, namely K and $\Phi((1,0,0)^T)$, both of which are semi-distinguished A-invariant. In this case, every nonzero vector of K is a distinguished generalized eigenvector of A corresponding to $\rho(A) \ (= 1)$. Also $m_{\rho(A)} = \nu_{\rho(A)}(A) = 3$, but it is impossible to find a chain of three distinct semi-distinguished A-invariant faces of K.

Example 5.5. Let K be a 3-dimensional proper cone whose intersection with the hyperplane $\{(\xi_1, \xi_2, \xi_3)^T : \xi_1 + \xi_2 + \xi_3 = 1\}$ is a convex set C lying inside the simplex conv $\{e_1, e_2, e_3\}$, where e_1, e_2, e_3 are the standard unit vectors of $\mathbb{R}^3$, and with the relative boundary formed by the line segment joining e_1 and e_2, together with some strictly convex smooth curve.

Let $A = J_2(0) \bigoplus J_1(0)$. (Note that, in fact, $A = e_1 e_2{}^T$.) It is straightforward to check that $A \in \pi(K)$ and also that K has three nonzero A-invariant faces, which are pairwise comparable, namely, $\Phi(e_1)$, $\Phi(e_1 + e_2)$ and K itself. Indeed, each of them is a semi-distinguished A-invariant face associated with $\rho(A) \ (= 0)$. So, in this case, the cardinality of a maximum chain of semi-distinguished A-invariant faces associated with $\rho(A)$ is 3 and is greater than $m_{\rho(A)}$, which is 2. Note that we also have

$$\mathrm{sp}_A(K) = (0, 2) = \mathrm{sp}_A(\Phi(e_1 + e_2)),$$

even though the A-invariant face $\Phi(e_1 + e_2)$ is properly included in the semi-distinguished A-invariant face K.

It is also worth noting that in this example the fact that $\rho(A) = 0$ is not a crucial condition. If we replace A by $A + I$, the example still works.

6. Semi-distinguished A-invariant faces

Certainly, a natural question to ask is, when a nonzero A-invariant face F of K is semi-distinguished A-invariant. Clearly F is a semi-distinguished A-invariant face of K if and only if F is a semi-distinguished $A|_{\operatorname{span} F}$-invariant face of itself. Thus, it is fundamental to consider the problem of when K is a semi-distinguished A-invariant face of itself. We have the following result which is motivated by the proof of Lemma 5.2.

Theorem 6.1. *Let K be a proper cone and let $A \in \pi(K)$. Consider the following conditions:*

(a) A^T has (up to multiples) a unique distinguished eigenvector for K^*.

(b) K is a semi-distinguished A-invariant face of itself.

(c) $\operatorname{sp}_A(K) \succ \operatorname{sp}_A(F)$ for all A-invariant faces F properly included in K.

We always have (a)$\Longrightarrow$(b) and (a)$\Longrightarrow$(c). If K^* is a facially exposed cone, then conditions (a), (b) and (c) are equivalent.

Proof.

(a)$\Longrightarrow$(b): When K^* contains a unique eigenvector of A^T, clearly $\rho(A)$ is the only distinguished eigenvalue of A^T for K^*. In this case, by [Tam 3, Theorem 5.1] K must contain in its interior a generalized eigenvector of A. So it suffices to establish the A-invariant join-irreducibility of K. Assume to the contrary that there exist A-invariant faces F_1, F_2 of K, both different from K, such that $K = F_1 \bigvee F_2$. Then $d_K(F_1)$, $d_K(F_2)$ are nonzero A^T-invariant faces of K^*, and hence must contain distinguished eigenvectors of A^T, say, z_1 and z_2 respectively. But

$$d_K(F_1) \bigwedge d_K(F_2) = d_K(F_1 \bigvee F_2) = d_K(K) = \{\mathbf{0}\},$$

so the vectors z_1 and z_2 are linearly independent. This contradicts condition (a).

(a)$\Longrightarrow$(c): Follows from the argument used in the second half of the proof of Lemma 5.2.

Now suppose, in addition, that K^* is a facially exposed cone.

(b)$\Longrightarrow$(a): Follows from the argument used in the first half of the proof of Lemma 5.2.

(c)$\Longrightarrow$(b): By condition (c) K is an A-invariant join-irreducible face of itself. Suppose that K is not semi-distinguished A-invariant. Then necessarily int K contains no generalized eigenvector of A. Hence, A^T has a distinguished eigenvalue for K^* other than $\rho(A)$, say λ, and let $z \in K^*$ be a corresponding eigenvector. Choose a distinguished eigenvector of A^T corresponding to $\rho(A)$ that is associated with a maximal block, say w. We contend that $w \in d_K \circ d_{K^*}(\Phi(z))$. Take any vector x from $d_{K^*}(\Phi(z))$. Since z is an eigenvector of A^T, $d_{K^*}(\Phi(z))$ is an A-invariant face of K, different from K. In view of condition (c), $\mathrm{sp}_A(x) \preceq \mathrm{sp}_A(d_{K^*}(\Phi(z))) \prec \mathrm{sp}_A(K) = (\rho(A), \nu_{\rho(A)}(A))$; so by Remark 4.12 we have $\langle x, w \rangle = 0$. This proves our contention. Note that $w \notin \Phi(z)$, as $\mathrm{sp}_{A^T}(w) = (\rho(A), 1) \not\prec (\lambda, 1) = \mathrm{sp}_{A^T}(z)$. Hence, we have $\Phi(z) \neq d_K \circ d_{K^*}(\Phi(z))$. In other words, $\Phi(z)$ is not an exposed face. This contradicts our hypothesis that K^* is a facially exposed cone.

$\square$

Our proof of Theorem 6.1, (c)$\Longrightarrow$(b) actually also establishes the following positive results:

Theorem 6.2. *Let K be a proper cone and let $A \in \pi(K)$. Suppose that $\mathrm{sp}_A(K) \succ \mathrm{sp}_A(F)$ for all A-invariant faces F properly included in K. If K is not a semi-distinguished A-invariant face of itself, then for any distinguished eigenvector z of A^T for K^* corresponding to a distinguished eigenvalue other than $\rho(A)$, $\Phi(z)$ is a non-exposed face of K^*.*

Corollary 6.3. *Let $A \in \pi(K)$, and suppose that $\mathrm{sp}_A(K) \succ \mathrm{sp}_A(F)$ for all A-invariant faces F properly included in K. If we have, for any non-exposed face G of K^*, the face $d_{K^*}(G)$ of K is not A-invariant, then K is a semi-distinguished A-invariant face of itself.*

It is worth noting that condition (a) of Theorem 6.1 is slightly weaker than the following equivalent condition for A^T to be K^*-irreducible:

A^T *has (up to multiples) a unique distinguished eigenvector for K^*, and this eigenvector lies in* $\operatorname{int} K^*$.

In general, conditions (b), (c) of Theorem 6.1 are logically independent. By Examples 5.3 and 5.5 respectively, we do not have the implications (c)$\Longrightarrow$(b) and (b)$\Longrightarrow$(c) (and hence also not (c)$\Longrightarrow$(a) and (b)$\Longrightarrow$(a)).

The following result clarifies the logical relations between a number of natural conditions on a cone-preserving map that involve the concepts of semi-distinguished A-invariant faces, distinguished generalized eigenvectors, and spectral pairs of faces.

Theorem 6.4. *Let $A \in \pi(K)$, and let λ be a distinguished eigenvalue of A for K. Consider the following conditions:*

(a)

(i) *Any A-invariant face of K which contains in its relative interior a generalized eigenvector of A corresponding to λ can be expressed as a join of semi-distinguished A-invariant faces associated with λ.*

(ii) *Let C denote the cone $K \bigcap \mathcal{N}((\lambda I - A)^n)$, and let B be the restriction map $A|_{\operatorname{span} C}$. For any semi-distinguished B-invariant face F of C, $\Phi(F)$ is a semi-distinguished A-invariant face of K.*

(b)

(i) *For each nonzero A-invariant face F of K associated with λ, there exists a semi-distinguished A-invariant face $G \subseteq F$ such that $\operatorname{sp}_A(G) = \operatorname{sp}_A(F)$.*

(ii) *For each nonzero A-invariant face F of K associated with λ, there exists in F a generalized eigenvector of A corresponding to λ of order $\nu_\lambda(A|_{\operatorname{span} F})$.*

(iii) *For each nonzero A-invariant face F of K associated with λ, F is a semi-distinguished A-invariant face, if $\operatorname{sp}_A(G) \prec \operatorname{sp}_A(F)$ for all A-invariant faces G properly included in F.*

(c) *For any A-invariant face F of K which contains in its relative*

interior a generalized eigenvector of A corresponding to λ, there exists a semi-distinguished A-invariant face G included in F such that $\mathrm{sp}_A(G) = \mathrm{sp}_A(F)$.

Then conditions (i), (ii) *given in* (a) (*and also conditions* (i)–(iii) *given in* (b)) *are equivalent. Furthermore, we have* (a)$\Longrightarrow$(c) *and* (b)$\Longrightarrow$(c).

Proof. First, we show that conditions (i), (ii) of (a) are equivalent.

(i)$\Longrightarrow$(ii): Let F be a semi-distinguished B-invariant face of C. Since F contains in its relative interior a generalized eigen-vector of A corresponding to λ, so does $\Phi(F)$; hence, by condition (i), we can write $\Phi(F)$ as $G_1 \vee \cdots \vee G_k$, where each G_i is a semi-distinguished A-invariant face of K associated with λ. If $k = 1$, we are done. So suppose that $k \geq 2$ and also that each G_i is properly included in $\Phi(F)$. It is straightforward to show that each $F_i \cap \mathcal{N}((\lambda I - A)^n)$ is a B-invariant face of C properly included in F, and also that the join (in C) of these faces is F. This contradicts our assumption on F.

(ii)$\Longrightarrow$(i): Consider any A-invariant face F of K which contains in its relative interior a generalized eigenvector of A corresponding to λ. Let G denote $F \cap \mathcal{N}((\lambda I - A)^n)$. Then G is a B-invariant face of C, and $\Phi(G) = F$. Now write G as the join of some B-invariant join-irreducible faces of C, say, $G_1, \cdots, G_k$. Since λ is the only eigenvalue of B, clearly the faces $G_1, \cdots, G_k$ are all semi-distinguished B-invariant. Then $F = \Phi(G) = \Phi(G_1) \vee \cdots \vee \Phi(G_k)$, where each $\Phi(G_i)$ is clearly associated with λ and, by condition (ii), is a semi-distinguished A-invariant face of K.

Next, we show that conditions (i), (ii) and (iii) of (b) are equivalent.

(i)$\Longrightarrow$(ii): Let F be an A-invariant face associated with λ, for which there exists, by condition (i), a semi-distinguished A-invariant face $G \subseteq F$ such that $\mathrm{sp}_A(G) = \mathrm{sp}_A(F)$. By definition of a semi-distinguished A-invariant face, there exists a generalized eigenvector x of A corresponding to $\rho_G = \rho_F = \lambda$ that lies in $\mathrm{relint}\, G$. The order of x as a generalized eigenvector of A is, by definition of the spectral pair of a face and by Theorem 4.4, equal to $\nu_\lambda(A|_{\mathrm{span}\, G})$, and hence to $\nu_\lambda(A|_{\mathrm{span}\, F})$, as $\mathrm{sp}_A(G) = \mathrm{sp}_A(F)$. Thus, x is the desired vector.

(ii)$\Longrightarrow$(iii): The given spectral pair condition on F clearly implies its A-invariant join-irreducibility. By condition (ii) F contains at least one generalized eigenvector of A, say x, corresponding to ρ_F $(= \lambda)$ of order $\nu_{\rho_F} (A|_{\operatorname{span} F})$. Replacing x by $(I + A)^{n-1}x$, if necessary, we may assume that $\Phi(x)$ is A-invariant. Since $\Phi(x) \subseteq F$ and $\operatorname{sp}_A(\Phi(x)) = (\rho_F, \nu_{\rho_F} (A|_{\operatorname{span} F})) = \operatorname{sp}_A(F)$, by the given condition on F, we have $\Phi(x) = F$, and hence $x \in \operatorname{relint} F$. This proves that F is semi-distinguished A-invariant.

(iii)$\Longrightarrow$(i): Let F be a nonzero A-invariant face associated with λ. Choose an A-invariant face G included in F minimal with respect to the property that $\operatorname{sp}_A(G) = \operatorname{sp}_A(F)$. In view of condition (iii), G must be semi-distinguished A-invariant. Hence, condition (i) follows.

(a)(i)$\Longrightarrow$(c): Follows from Theorem 4.9(i)(c).

(b)(i)$\Longrightarrow$(c): Obvious.

<div align="right">□</div>

The proof of the implication (i)$\Longrightarrow$(ii) in Theorem 6.4 (b) actually establishes the following result:

Remark 6.5. Given a nonzero A-invariant face F of K, if there exists a semi-distinguished A-invariant face G included in F such that $\operatorname{sp}_A(G) = \operatorname{sp}_A(F)$, then there exists in F a generalized eigenvector of A corresponding to ρ_F of order $\nu_{\rho_F} (A|_{\operatorname{span} F})$.

As we shall show in Example 8.1 of Section 8, the converse of Remark 6.5 does not hold.

Some further remarks about the conditions (a), (b) and (c) of Theorem 6.4 are in order. In general, we do not have the implication (a)$\Longrightarrow$(b). As one can readily check, for the A and K of Example 5.3, with $\lambda = \rho(A)$, condition (a)(i) is satisfied, but not condition (b)(i). Whether the implication (b)$\Longrightarrow$(a) holds or not is *unknown* to us. In Example 8.2 we shall show that the implications (c)$\Longrightarrow$(a) and (c)$\Longrightarrow$(b) both do not hold.

If K is a proper cone with the property that the dual cone of each of its

faces is a facially exposed cone and if $A \in \pi(K)$, then according to Theorem 6.1, for any nonzero A-invariant face F of K, F is semi-distinguished A-invariant if and only if $\mathrm{sp}_A(F) \succ \mathrm{sp}_A(G)$ for all A-invariant faces G properly included in F; thus, for all distinguished eigenvalues λ of A, condition (b) (and hence also condition (c)) of Theorem 6.4 is satisfied. Clearly proper cones K all of whose nontrivial faces are polyhedral and for which K^* are facially exposed cones have the property. Such cones include all polyhedral cones, proper cones of $\mathbb{R}^3$ whose dual cones are facially exposed, and also strictly convex smooth cones. [Recall that a proper cone K is said to be *strictly convex* if each of its nontrivial faces is one-dimensional, and is *smooth* if for each nonzero boundary vector x of K, $\dim d_K(\Phi(x)) = 1$. It can be shown that the class of strictly convex cones whose dual cones are facially exposed is the same as the class of strictly convex smooth cones.].

Perfect cones form another interesting class with the above-mentioned property. Following [Bar 1], we call a proper cone a *perfect cone* if each of its faces is self-dual in its own linear span. Examples of perfect cones include, the nonnegative orthant $\mathbb{R}^n_+$, the n-dimensional ice-cream cone $K_n :=$ $\{(\xi_1, \cdots, \xi_n)^T : \xi_1 \geq (\xi_2{}^2 + \cdots + \xi_n{}^2)^{1/2}\}$, and the cone of $n{\times}n$ positive semi-definite hermitian (or real symmetric) matrices. An equivalent definition for K to be a perfect cone is that K is self-dual, and for each face F of K, the orthogonal projection p_F of $\mathbb{R}^n$ onto $\mathrm{span}\, F$ belongs to $\pi(K)$ (see [Bar 1, Proposition 1]). So a perfect cone is an orthogonal projectionally exposed, and hence a projectionally exposed cone (see [Su–T] for definitions). But by [Su–T, Corollary 4.4 and Lemma 2.2] each face of a projectionally exposed cone is a facially exposed cone in its own right. Hence, each face of a perfect cone is itself a facially exposed self-dual cone.

For each nonnegative integer n, we use $P(n)$ to denote the cone of all real polynomials of degree not exceeding n that are nonnegative on the closed interval $[0, 1]$. In [B–T] it is proved that $P(n)^*$ is always a facially exposed cone, and also that each nonzero face of $P(n)$ is linearly isomorphic with $P(m)$ for some nonnegative integer $m \leq n$. Thus, the cone $P(n)$ also serves

as another interesting example of a proper cone with the property that the dual cone of each of its faces is a facially exposed cone.

To sum up our preceding discussions, we have the following result.

Theorem 6.6.

(i) *Let K be a proper cone with the property that the dual cone of each of its faces is a facially exposed cone, and let $A \in \pi(K)$. Then for any nonzero A-invariant face F of K, F is semi-distinguished A-invariant if and only if $\mathrm{sp}_A(G) \prec \mathrm{sp}_A(F)$ for all A-invariant faces G properly included in F. Consequently, for all distinguished eigenvalues λ of A, condition (b) (and hence (c)) of Theorem 6.4 is satisfied.*

(ii) *A proper cone K has the property given in the hypothesis of part (i), if it fulfills one of the following conditions:*

(a) *K^* is a facially exposed cone, and all nontrivial faces of K are polyhedral (which is the case, if K is polyhedral, or is a strictly convex smooth cone).*

(b) *K is a perfect cone.*

(c) *K equals $P(n)$ for some nonnegative integer n.*

Note that we could have formulated the last part of Theorem 6.6 (i) without mentioning the distinguished eigenvalues of A. Indeed, the statement that, for all distinguished eigenvalues λ of A, condition (b) (ii) of Theorem 6.4 is satisfied amounts to saying that for each nonzero A-invariant face F of K, there exists in F a distinguished generalized eigenvector of A corresponding to ρ_F of order $\nu_{\rho_F}(A|_{\mathrm{span}\,F})$. We leave it to the reader to give similar reformulations for the statement that conditions (b) (ii), (iii) or (c) of Theorem 6.4 are satisfied for all distinguished eigenvalues λ of A.

Theorem 6.7. *Let $A \in \pi(K)$, where K is a polyhedral cone or a strictly convex cone. Then for any distinguished eigenvalue λ of A, condition (a) of Theorem 6.4 is satisfied.*

The polyhedral case of Theorem 6.7 is covered by Lemma 6.8. The proof for a strictly convex cone will follow from Lemma 6.10.

Lemma 6.8. *Let K be a polyhedral cone. Let $A \in \pi(K)$, and let λ be a distinguished eigenvalue of A for K. Let C denote the cone $K \bigcap \mathcal{N}((\lambda I - A)^n)$, and let B denote the restriction map $A|_{\text{span } C}$. Then for any semi-distinguished B-invariant face F of C, $\Phi(F)$ is a semi-distinguished A-invariant face of K.*

Proof. Since K is polyhedral, by Theorem 6.6 it suffices to show that $\text{sp}_A(G) \prec \text{sp}_A(\Phi(F))$ for any A-invariant face G properly included in $\Phi(F)$. If $\rho_G < \lambda$, clearly there is no problem. So, suppose that $\rho_G = \lambda$. By Theorem 6.6 again, condition (b) (i) of Theorem 6.4 is satisfied. Hence, there exists a semi-distinguished A-invariant face H included in G such that $\text{sp}_A(H) = \text{sp}_A(G)$. Then $H \bigcap \mathcal{N}((\lambda I - A)^n)$ is a B-invariant face of C properly included in F. Since F is a semi-distinguished B-invariant face of the polyhedral cone C, by Theorem 6.6 again we have $\text{sp}_B(H \bigcap \mathcal{N}((\lambda I - A)^n))$ $\prec \text{sp}_B(F)$. Now relint $F \subseteq$ relint $\Phi(F)$ and B is a restriction of A; so by the definition of the spectral pair of a face, we have $\text{sp}_B(F) = \text{sp}_A(\Phi(F))$. But H contains in its relative interior a generalized eigenvector of A corresponding to λ, so for a similar reason, we also have $\text{sp}_B(H \bigcap \mathcal{N}((\lambda I - A)^n)) = \text{sp}_A(H)$. Hence, the desired inequality $\text{sp}_A(G) \prec \text{sp}_A(\Phi(F))$ follows. $\square$

For completeness, we also note that the converse of Lemma 6.8 always holds, even without the polyhedrality assumption on K. The proof is straightforward.

Remark 6.9. Let $A \in \pi(K)$ and let λ be a distinguished eigenvalue of A for K. Let C denote the cone $K \bigcap \mathcal{N}((\lambda I - A)^n)$ and let B denote the restriction map $A|_{\text{span } C}$. For any face F of C, if $\Phi(F)$ is a semi-distinguished A-invariant face of K, then F is a semi-distinguished B-invariant face of C.

Lemma 6.10. *Let K be a strictly convex cone, and let $A \in \pi(K)$. For any A-invariant face F of K, we have $\mathrm{sp}_A(F) \succ \mathrm{sp}_A(G)$ for all A-invariant faces G properly included in F, whenever F is a semi-distinguished A-invariant face of K.*

Proof. It is clear that each nontrivial A-invariant face of K, being an extreme ray of K, is a distinguished A-invariant face and satisfies trivially the desired property involving spectral pairs. So it suffices to consider the case $F = K$. If $\nu_{\rho(A)}(A) > 1$, then for any nonzero A-invariant face G properly included in K, we have,

$$\mathrm{sp}_A(K) = (\rho(A), \nu_{\rho(A)}(A)) \succ (\rho(A), 1) \succeq (\rho_G, 1) = \mathrm{sp}_A(G),$$

where the last equality holds as G is an extreme ray. So suppose that $\nu_{\rho(A)}(A) = 1$. Then the generalized eigenvector of A (corresponding to $\rho(A)$) that lies in int K is in fact an eigenvector. Hence, condition (d) of Theorem 4.11 is satisfied; that is, K is a distinguished A-invariant face of itself, and so we also have $\mathrm{sp}_A(K) \succ \mathrm{sp}_A(G)$ for any A-invariant face G properly included in K. $\square$

We now give the proof of Theorem 6.7 for the strictly convex case:

Clearly it suffices to show that if K contains in its interior a generalized eigenvector of A then K can be expressed as a join of semi-distinguished A-invariant faces associated with $\rho(A)$. If $\nu_{\rho(A)}(A) > 1$ then, as shown in the proof of Lemma 6.10, we have $\mathrm{sp}_A(K) \succ \mathrm{sp}_A(G)$ for all A-invariant faces G properly included in K; hence, K is A-invariant join-irreducible, and since K contains in its interior a generalized eigenvector of A, K is itself a semi-distinguished A-invariant face. When $\nu_{\rho(A)}(A) = 1$, we have either K is a distinguished A-invariant face of itself, or $\dim(K \cap \mathcal{N}(\rho(A)I - A)) \geq 2$. In the former case, we are done. In the latter case, since K is strictly convex, clearly K can be expressed as the join of two A-invariant extreme rays, and

hence of two A-invariant distinguished faces, associated with $\rho(A)$.

For completeness, we also include the following interesting result on a smooth cone.

Lemma 6.11. *Let K be a smooth cone, and let $A \in \pi(K)$.*

(i) *If $\nu_{\rho(A)}(A) > 1$, then K contains in its interior a generalized eigenvector of A.*

(ii) *There always exists in K a generalized eigenvector of A of order $\nu_{\rho(A)}(A)$ corresponding to $\rho(A)$.*

(iii) *If $\mathrm{sp}_A(K) \succ \mathrm{sp}_A(G)$ for all A-invariant faces G properly included in K, then K is a semi-distinguished A-invariant face of itself.*

Proof.

(i): Assume to the contrary that K does not contain in its interior a generalized eigenvector of A. By [Tam 3, Theorem 5.1] A^T has a distinguished eigenvalue λ other than $\rho(A)$. Let $w \in K^*$ be a corresponding eigenvector. Choose from K an eigenvector x of A corresponding to $\rho(A)$, which is associated with a maximal Jordan block (see Remark 4.2). Also choose from K^* an eigenvector z of A^T corresponding to $\rho(A)$, which is again associated with a maximal Jordan block. Since x and w are respectively eigenvectors of A and A^T corresponding to distinct eigenvalues, x and w are mutually orthogonal. Because the size of a maximal Jordan block of A corresponding to $\rho(A)$, i.e. $\nu_{\rho(A)}(A)$, is greater than 1, the vectors x and z are also mutually orthogonal. Thus x is orthogonal to two linearly independent vectors of K^*. This contradicts the smoothness of K at x.

(ii): If $\nu_{\rho(A)}(A) = 1$, clearly there is no problem. If $\nu_{\rho(A)}(A) > 1$, our assertion follows from part (i).

(iii): If $\nu_{\rho(A)}(A) = 1$, then by the spectral pair condition on K, clearly K is a distinguished A-invariant face of itself. Otherwise, by part (i) K contains in its interior a generalized eigenvector of A. And since the spectral pair condition on K implies the A-invariant join-irreducibility of K, it follows

that K is a semi-distinguished A-invariant face of itself.

$\square$

The following example shows that parts (i)–(iii) of Lemma 6.11 all do not hold, if in the hypothesis on K, "smooth" is replaced by "strictly convex". Consequently, the converse of Lemma 6.10 also does not hold.

Example 6.12. Let α be a positive real number less than 1. Let f be a real-valued function defined on the real line that possesses the following properties:

(i) f is a differentiable convex function;

(ii) $\lim\limits_{\xi \to -\infty} f(\xi) = \infty$;

(iii) $\lim\limits_{\xi \to \infty} f(\xi) = -\infty$;

(iv) $\lim\limits_{\xi \to \infty} f'(\xi) = 0$;   and

(v)   For each $\xi \in \mathbb{R}$, we have $f(\xi + 1) \leq \alpha f(\xi)$.

For instance, if $e^{-1} < \alpha < 1$ and f is given by:

$$f(\xi) = \left\{ \begin{array}{ll} -\log(\xi + 1) & \text{for} \quad \xi \geq 0 \\ \exp(-\xi) - 1 & \text{for} \quad \xi < 0 \end{array} \right. ,$$

then one can readily verify that f possesses properties (i)–(v).

Denote the epigraph of f, i.e. the set $\{(\xi_1, \xi_2)^T \in \mathbb{R}^2 : \xi_2 \geq f(\xi_1)\}$, by epi f. Since f is a continuous convex function, epi f is a closed convex set. By the convexity of f and property (v), for any $\xi \in \mathbb{R}$, we have, $f'(\xi) \leq f(\xi + 1) - f(\xi) \leq -(1 - \alpha)f(\xi)$. In view of property (ii) it follows that $\lim_{\xi \to -\infty} f'(\xi) = -\infty$. The latter condition implies that the recession cone $\mathbf{0}^+(\text{epi } f)$ cannot contain a vector of the form $(\nu_1, \nu_2)^T$ with $\nu_1 < 0$. Similarly, property (iv) implies that $\mathbf{0}^+(\text{epi } f)$ cannot contain a vector of the form $(\nu_1, \nu_2)^T$ with $\nu_2 < 0$. Clearly, $(0, 1)^T \in \mathbf{0}^+(\text{epi } f)$. Also, we have, $(1, 0)^T \in \mathbf{0}^+(\text{epi } f)$; otherwise, f is not one-to-one and property (iii) cannot be met. Thus, $\mathbf{0}^+(\text{epi } f)$ equals $\mathbb{R}^2_+$.

Let K be the proper cone of $\mathbb{R}^3$ whose dual cone K^* is given by:

$$K^* = \{\lambda(\xi_1, \xi_2, 1)^T \in \mathbb{R}^3 : \lambda \geq 0, \ (\xi_1, \xi_2)^T \in \operatorname{epi}(f)\} \bigcup (\mathbf{0}^+(\operatorname{epi} f) \times \{0\}).$$

Since f is a differentiable function, K^* is smooth at each nonzero boundary vector of the form $\lambda(\xi_1, \xi_2, 1)^T$. To show that K^* is smooth at $(1, 0, 0)^T$, let $(\eta_1, \eta_2, \eta_3)^T$ be a nonzero vector of K which is orthogonal to $(1, 0, 0)^T$. Clearly, $\eta_1 = 0$. Since $(0, 1, 0)^T \in K^*$, $\eta_2 \geq 0$. If $\eta_2 > 0$, then in view of property (iii), we can find some $\xi \in \mathbb{R}$ such that the inner product between $(\eta_1, \eta_2, \eta_3)^T$ and $(\xi, f(\xi), 1)^T$ is negative, which is a contradiction. It follows that (up to multiples) $(0, 0, 1)^T$ is the only vector of K orthogonal to $(1, 0, 0)^T$. Similarly, we can show that $(0, 0, 1)^T$ is also the only vector of K orthogonal to $(0, 1, 0)^T$. This shows that K^* is a smooth cone. Hence, K is a strictly convex cone.

Now let

$$A = \begin{bmatrix} 1 & 0 & 0 \\ 0 & \alpha & 0 \\ 1 & 0 & 1 \end{bmatrix}.$$

By property (v) one readily checks that $A^T \in \pi(K^*)$; hence, $A \in \pi(K)$. Clearly, $\nu_{\rho(A)}(A) = 2$. Note that K does not contain a generalized eigenvector of A corresponding to $\rho(A)$ of order two; because, any such vector is necessarily orthogonal to the vector $(0, 1, 0)^T$ of K^*, contradicting what we have found above. It is now clear that K is not a semi-distinguished A-invariant face of itself, and also that we have $\operatorname{sp}_A(K) \succ \operatorname{sp}_A(G)$ for all A-invariant faces G properly included in K.

7. EXTENSIONS OF
TWO NONNEGATIVE MATRIX RESULTS

Besides Theorem B (mentioned in Section 1), the following is another early result on the combinatorial spectral theory of a nonnegative matrix:

Theorem C. ([Schn 1, Theorem 3]). *If P is a nonnegative matrix, then $\nu_{\rho(P)}(P) = 1$ if and only if there are no comparable basic classes of P.*

It is clear that Theorem C follows as a special case of Theorem A, the Rothblum Index theorem.

For a general cone-preserving map, we have the following result related to Theorem C.

Theorem 7.1. *Let $A \in \pi(K)$, and let λ be a distinguished eigenvalue of A for K. Denote by m_λ the maximal order of distinguished generalized eigenvectors of A corresponding to λ. Consider the following conditions:*

(a) *$m_\lambda = 1$.*

(b) *Any two distinct semi-distinguished A-invariant faces of K associated with λ are noncomparable.*

(i) *We always have* (a)$\Longrightarrow$(b).

(ii) *When condition* (c) (*and hence also when conditions* (a) *or* (b)) *of Theorem 6.4 is satisfied, conditions* (a) *and* (b) *are equivalent.*

Proof.

(i): It is clear that any two distinct distinguished A-invariant faces of K associated with λ are noncomparable. So it suffices to show that, when $m_\lambda = 1$, any semi-distinguished A-invariant face associated with λ is distinguished A-invariant. Indeed, if F is a semi-distinguished A-invariant face associated with λ, then by definition F is A-invariant join-irreducible and contains in its relative interior a generalized eigenvector of A corresponding to λ. Since $m_\lambda = 1$, this generalized eigenvector is necessarily an eigenvector. Hence, by Theorem 4.11 F must be a distinguished A-invariant face of K associated with λ. This establishes (b).

(ii): It suffices to establish the implication (b)$\Longrightarrow$(a). Assume to the contrary that condition (b) is satisfied, but not condition (a). Then $m_\lambda > 1$. Let x be a distinguished generalized eigenvector of A corresponding to λ of order m_λ. Then $F = \Phi((I + A)^{n-1}x)$ is an A-invariant face that contains in its relative interior a generalized eigenvector of A corresponding to λ. Furthermore, $\mathrm{sp}_A(F) = (\lambda, m_\lambda)$. By condition (c) of Theorem 6.4 there exists a semi-distinguished A-invariant face G included in F such that $\mathrm{sp}_A(G) =$

50

$\mathrm{sp}_A(F)$. Now choose any extremal distinguished eigenvector u of A corresponding to λ that lies in G. Then by Theorem 4.11 $\Phi(u)$ is a distinguished, and hence semi-distinguished, A-invariant face associated with λ which is properly included in G. This contradicts condition (b).

$\square$

Later, by Example 8.1 we shall show that for the conditions (a), (b) of Theorem 7.1, the implication (b)$\Longrightarrow$(a) is not valid in general.

In related to Theorem B we have the following result.

Theorem 7.2. *Let $A \in \pi(K)$, and let λ be a distinguished eigenvalue of A for K. Consider the following conditions:*

(a) $\dim \mathcal{N}(\lambda I - A) = 1$.

(b) *Any A-invariant face which contains in its relative interior a generalized eigenvector of A corresponding to λ is semi-distinguished A-invariant.*

(c) *Any two A-invariant faces of K each containing in its relative interior a generalized eigenvector of A corresponding to λ are comparable.*

(d) *Any two semi-distinguished A-invariant faces of K associated with λ are comparable.*

(e) $\dim \mathrm{span}\,[\mathcal{N}(\lambda I - A) \bigcap K] = 1$.

(i) *We always have the implications*

$\qquad$ (a)$\Longrightarrow$(b)$\Longrightarrow$(c)$\Longrightarrow$(d)$\Longrightarrow$(e).

(ii) *When condition (a) of Theorem 6.4 is satisfied, conditions (b), (c) and (d) are equivalent.*

(iii) *When K is polyhedral, conditions (b), (c) and (d) are equivalent. If, in addition, $\lambda = \rho(A)$, then condition (a) is also another equivalent condition.*

Proof.

(i):

(a)$\Longrightarrow$(b): We are required to show that if F is any A-invariant face of K that contains in its relative interior a generalized eigenvector of A

51

corresponding to λ, then F is A-invariant join-irreducible. By considering the restriction map $A|_{\mathrm{span}\,F}$ instead of A, we may henceforth take F to be K and λ to be $\rho(A)$. Let G be any A-invariant face of K properly included in K. We are going to show that $\mathrm{sp}_A(G) \prec \mathrm{sp}_A(K)$. Once this is done, the A-invariant join-irreducibility of K will follow.

Now $\mathrm{span}\,G$ is an A-invariant subspace of $\mathbb{R}^n$. If $\mathrm{span}\,G$ contains a generalized eigenvector of A corresponding to $\rho(A)$ of order $\nu_{\rho(A)}(A)$, then $\mathrm{span}\,G$ will include $\mathcal{N}((\rho(A)I - A)^n)$, as the Jordan form of A has only one block corresponding to $\rho(A)$. Since $G = K \bigcap \mathrm{span}\,G$ and $\mathcal{N}((\rho(A)I - A)^n)$ meets the interior of K, it will follow that G contains an interior vector of K and hence is equal to K, which is a contradiction. We just show that if $\rho(A)$ is an eigenvalue of $A|_{\mathrm{span}\,G}$ then its index is less than $\nu_{\rho(A)}(A)$. Now it is clear that we have $\mathrm{sp}_A(G) \prec \mathrm{sp}_A(K)$.

(b)$\Longrightarrow$(c): Assume to the contrary that there exist two noncomparable A-invariant faces of K, say F_1, F_2, each containing in its relative interior a generalized eigenvector of A corresponding to λ. Then $F_1 \bigvee F_2$ is an A-invariant face with the same property, but is not semi-distinguished A-invariant. This contradicts condition (b).

(c)$\Longrightarrow$(d): Obvious.

(d)$\Longrightarrow$(e): If $\dim[\mathcal{N}(\lambda I - A)\bigcap K] \geq 2$, choose any two distinct extreme vectors x_1, x_2 of the cone $\mathcal{N}(\lambda I - A)\bigcap K$. Then $\Phi(x_1)$ and $\Phi(x_2)$ are distinguished, and hence semi-distinguished, noncomparable A-invariant faces of K associated with λ. This violates condition (d).

(ii): To prove the equivalence of conditions (b), (c), (d), it suffices to establish the implication (d)$\Longrightarrow$(b). Let F be an A-invariant face which contains in its relative interior a generalized eigenvector of A corresponding to λ. By condition (a)(i) of Theorem 6.4 we can write F as $F_1 \bigvee \cdots \bigvee F_k$, where each F_i is a semi-distinguished A-invariant face associated with λ. We may assume that there is no redundant terms in this representation of F. If $k \geq 2$, then F_1 and F_2 will be two noncomparable semi-distinguished A-invariant faces associated with λ, contradicting condition (d). Hence, we

have $k = 1$ and F is semi-distinguished A-invariant.

(iii): When K is polyhedral, by Theorem 6.7 condition (a) of Theorem 6.4 is satisfied. Hence, by part (ii), conditions (b), (c) and (d) are equivalent.

Now suppose, in addition, that $\lambda = \rho(A)$. To prove the equivalence of conditions (a)–(d), it remains to establish the implication (d)$\Longrightarrow$(a).

Suppose that condition (d) is satisfied. Clearly an equivalent condition for (a) is that the geometric multiplicity of $\rho(A)$ as an eigenvalue of $A|_{\mathcal{N}((\rho(A)I-A)^n)}$ is one. Since K is polyhedral, $\mathcal{N}((\rho(A)I - A)^n)$ has a basis that consists of vectors of K (see [Tam 3, Theorem 7.5]); so $\mathcal{N}((\rho(A)I - A)^n) \bigcap K$ is a proper cone of $\mathcal{N}((\rho(A)I - A)^n)$. Denote by B the restriction of A to $\mathcal{N}((\rho(A)I - A)^n)$ and by C the cone $\mathcal{N}((\rho(A)I - A)^n) \bigcap K$. If G_1, G_2 are semi-distinguished B-invariant faces of C, then by Lemma 6.8 $\Phi(G_1)$ and $\Phi(G_2)$ are semi-distinguished A-invariant faces of K and are comparable according to condition (d). But $G_i = \mathcal{N}((\rho(A)I - A)^n) \bigcap \Phi(G_i)$ for $i = 1, 2$, hence G_1 and G_2 are also comparable. This shows that $B \; [\in \pi(C)]$ also satisfies the condition corresponding to condition (d). Therefore, by considering B instead of A, we may, henceforth, assume that $\rho(A)$ is the only eigenvalue of A.

Since K is polyhedral, by Theorem 6.7, condition (a)(i) of Theorem 6.4 is satisfied; hence, any nonzero A-invariant face of K (which necessarily contains in its relative interior a generalized eigenvector of A corresponding to $\rho(A)$) is the join of semi-distinguished A-invariant faces of K (associated with $\rho(A)$). But according to condition (d), any two semi-distinguished A-invariant faces of K are comparable. It follows that each nonzero A-invariant face of K is semi-distinguished. In particular, K is a semi-distinguished A-invariant face of itself. Hence, by Theorem 6.1 A^T has (up to multiples) a unique distinguished eigenvector for K^*, say w. Indeed, as noted in the proof of Lemma 5.2, in this case A^T has precisely one maximal Jordan block corresponding to $\rho(A)$ and w is associated with this maximal block. Furthermore, since $\rho(A)$ is the only eigenvalue of A, we have $(\mathrm{span}\,\{w\})^{\perp} = E_{\nu-1}$, where $E_{\nu-1}$ is the space of generalized eigenvectors of A (corresponding to

$\rho(A)$) of order less than or equal to $\nu_{\rho(A)}(A)-1$, together with the zero vector. We contend that $\Phi(w)$ is an extreme ray of K^*.

To show this, choose a nonzero extreme vector z of $\Phi(w)$. Then we have

$$(\rho(A), 1) = \mathrm{sp}_{A^T}(\Phi(w)) \succeq \mathrm{sp}_{A^T}(\Phi(z)) \succeq (\rho(A), 1),$$

where the last inequality follows from the assumption that $\rho(A)$ is the only eigenvalue of A. Hence, $\mathrm{sp}_{A^T}(\Phi(z)) = (\rho(A), 1)$ and so z is an eigenvector of A^T. It follows that z is a multiple of w. This proves our contention.

Since K is polyhedral and $\Phi(w)$ is an extreme ray of K^*, $d_{K^*}(\Phi(w))$ must be a cone of dimension $n-1$ (for reference, see [Tam 1, Theorem 3]), and hence is a proper cone of $E_{\nu-1}$; thus we can write $A|_{E_{\nu-1}} \in \pi(d_{K^*}(\Phi(w)))$. Now let the Jordan form of A be

$$J_{i_1}(\rho(A)) \oplus J_{i_2}(\rho(A)) \oplus \cdots \oplus J_{i_k}(\rho(A)),$$

where $k \geq 1$, and $i_1 > i_2 \geq \cdots \geq i_k$ if $k \geq 2$. Then it is not difficult to show that the Jordan form of $A|_{E_{\nu-1}}$ is

$$J_{i_1-1}(\rho(A)) \oplus J_{i_2}(\rho(A)) \oplus J_{i_3}(\rho(A)) \oplus \cdots \oplus J_{i_k}(\rho(A)).$$

Note that $d_{K^*}(\Phi(w))$ is itself a polyhedral cone, and also that $A|_{E_{\nu-1}}$ inherits from A the condition corresponding to condition (d). So, applying our above argument with $A|_{E_{\nu-1}}$ in place of A, we see that the Jordan form of $A|_{E_{\nu-1}}$ also has precisely one maximal block. Suppose $k \geq 2$. If $i_1 - 1 = i_2$, we already obtain a contradiction. Otherwise, our argument shows that $A|_{E_{\nu-2}}$, where $E_{\nu-2}$ denotes the space of generalized eigenvectors of A of order less than or equal to $\nu_{\rho(A)}(A) - 2$, together with the zero vector, belongs to $\pi(G)$ for some A-invariant face G of K of dimension $n-2$. Furthermore, $A|_{E_{\nu-2}}$ also has precisely one maximal block in its Jordan form, which is

$$J_{i_1-2}(\rho(A)) \oplus J_{i_2}(\rho(A)) \oplus \cdots \oplus J_{i_k}(\rho(A)).$$

If $i_1 - 2 = i_2$, we again arrive at a contradiction. Otherwise, we repeat the process and obtain a contradiction after a finite number of steps. This shows

that $k = 1$, i.e. A has precisely one Jordan block (corresponding to $\rho(A)$), as desired.

$\square$

In related to the conditions of Theorem 7.2 one may also consider the following condition:

(f) Any two A-invariant faces of K associated with λ are comparable.

Clearly condition (f) implies condition (c) of Theorem 7.2. On the other hand, condition (f) is logically independent of condition (a) of Theorem 7.2. To see why condition (a) does not imply condition (f), consider the 3×3 nonnegative matrix A given by:

$$A = \begin{bmatrix} 1 & 1 & 1 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix}.$$

Take $\lambda = \rho(A)$. Clearly $\rho(A) = 1$ and the geometric multiplicity of 1 as an eigenvalue of A is 1. However, $\Phi(e_1 + e_2)$ and $\Phi(e_1 + e_3)$ are noncomparable A-invariant faces of $\mathbb{R}^3_+$ associated with 1. So, in this case, condition (a) of Theorem 7.2 is satisfied, but not condition (f). Example 5.5 can be used to show that the implication (f)$\Longrightarrow$(a) also does not hold. It is not clear to us whether condition (f) is sufficient for condition (b) of Theorem 7.2.

Now we give some further remarks in concern with conditions (a)–(e) of Theorem 7.2.

When $\lambda = \rho(A)$ and A is a nonnegative matrix, by Theorem 7.2 (iii) conditions (a)–(d) are all equivalent. However, condition (e) is a strictly weaker condition. To see this, consider the following 4×4 nilpotent nonnegative matrix:

$$A = \begin{bmatrix} 0 & 1 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 \end{bmatrix}.$$

In this case, each of the singletons $\{1\}, \{2\}, \{3\}$ and $\{4\}$ is a class, indeed a

basic class, of A. Also, $\{1\}$ is the only distinguished class of A (associated with 0). By the Frobenius-Victory theorem, we have $\dim(\mathcal{N}(A) \cap \mathbb{R}_+^n) = 1$; that is, condition (e) is satisfied for $\lambda = 0$. (In fact, in this case, for a similar reason, the dual condition that $\dim(\mathcal{N}(A^T) \cap \mathbb{R}_+^n) = 1$ is also satisfied.) However, condition (a) is not satisfied for $\lambda = 0$, because $\dim \mathcal{N}(A) = 4 - \text{rank}\,(A) = 2$.

In Section 8 we shall give examples which show that the missing implications of Theorem 7.2 all do not hold in general.

The following example shows that when $\lambda < \rho(A)$, condition (b) of Theorem 7.2 and the corresponding condition with A replaced by A^T and K replaced by K^* together do not imply condition (a), not even for the nonnegative matrix case, assuming that λ is a distinguished eigenvalue of A for K and also of A^T for K^*.

Example 7.3. Consider the following 4×4 nonnegative matrix:

$$
A = \begin{bmatrix} 0 & 0 & 0 & 0 \\ 1 & 1 & 1 & 0 \\ 1 & 1 & 2 & 0 \\ 1 & 1 & 1 & 0 \end{bmatrix}.
$$

In this case A has precisely three classes which form a chain, namely, $\{4\}, \{2,3\}$ and $\{1\}$; $\{2,3\}$ being a basic class, and $\{1\}$ and $\{4\}$ being nonbasic classes both associated with 0. Clearly $\mathbb{R}_+^4$ has precisely three nonzero A-invariant faces, namely, $\Phi(e_4)$, $\Phi(e_2 + e_3 + e_4)$ and $\mathbb{R}_+^4$ itself. Also, $\Phi(e_4)$ is the only A-invariant face of $\mathbb{R}_+^4$ associated with 0, indeed, a semi-distinguished A-invariant face; thus condition (b) of Theorem 7.2 is satisfied by A for $\lambda = 0$. For a similar reason, A^T also satisfies the corresponding condition. However, condition (a) of Theorem 7.2 is not satisfied, because we have $\dim \mathcal{N}(A) = 4 - \text{rank}\,A = 2$.

In the nonpolyhedral case, even when K is the n-dimensional ice-cream cone K_n (which is a perfect cone, and possesses many nice properties as described in Theorem 6.6) and $\lambda = \rho(A)$, condition (b) of Theorem 7.2

and the corresponding condition for A^T together do not guarantee condition (a). For instance, take A to be yz^T, where y and z are any two mutually orthogonal nonzero vectors that lie in ∂K_n. Then as can be readily seen, $\Phi(y)$ and K_n itself are the only nonzero A-invariant faces of K_n, both being semi-distinguished A-invariant. So condition (b) of Theorem 7.2 is satisfied. For a similar reason, A^T also satisfies the corresponding condition. However, A does not satisfy condition (a), because

$$\dim \mathcal{N}(\rho(A)I - A) = \dim \mathcal{N}(A) = n - \operatorname{rank} A = n - 1 \geq 2.$$

Conceivably, the geometry of K affects the spectral properties of its cone-preserving maps. We just mention two such results on a rank-one cone-preserving map, whose proofs are not difficult.

Theorem 7.4. *Given $\mathbf{0} \neq y \in K$ and $\mathbf{0} \neq z \in K^*$ such that $z^T y = 0$. Let $A = yz^T$. Then for $\lambda = \rho(A)$, conditions* (b), (c) *and* (d) *of Theorem 7.2 are equivalent, and the following is another equivalent condition:*

(a)$'$ *y is an exposed extreme vector of K such that $\Phi(y) = d_{K^*}(\Phi(z))$ and the set of all faces of K that contain y forms a chain.*

Theorem 7.5. *Let y and z be nonzero vectors of ∂K and ∂K^* respectively, and let $A = yz^T$. The following conditions are equivalent:*

(a) *K is an A-invariant join-irreducible face of itself.*

(b) *y belongs to precisely one maximal face of K, which also includes $d_{K^*}(\Phi(z))$.*

If, in addition, the vectors y and z are orthogonal, then the following is another equivalent condition:

(c) *y belongs to precisely one maximal face of K.*

8. Further examples

Example 8.1.

Let $A = \begin{bmatrix} 1 & 1 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & \alpha \end{bmatrix}$, where $0 < \alpha < 1$.

Let K_1, K_2 be convex cones of $\mathbb{R}^4$ given by:

$$K_1 = \text{pos}\,\{e_1, A^i(e_2 - e_4), i = 0, 1, \cdots\},$$
$$\text{and} \quad K_2 = \text{pos}\,\{e_1, A^i(e_2 + e_3 + e_4), i = 0, 1, \cdots\},$$

where $e_1, \cdots, e_4$ are the standard unit vectors of $\mathbb{R}^4$. Also let $K = K_1 + K_2$. Clearly K_1, K_2 are closed, pointed cones, and K is a full cone of $\mathbb{R}^4$. As can be easily seen, $K_1 \bigcap (-K_2) = \{\mathbf{0}\}$. So by [Roc, Corollary 9.1.2] K is a closed, pointed, full, and hence a proper cone of $\mathbb{R}^4$. Since K_1 and K_2 are both invariant under A, we have $A \in \pi(K)$. Note that the vector e_1 (and its nonnegative multiples) is the only common vector of K_1 and K_2. Except for the vector e_1, the second component of each vector in K_1 is always positive and the third component is always zero. On the other hand, the second and the third component of each vector in K_2, except for the vector e_1, are always equal and positive. With these observations in mind, it is straightforward to verify that K_1 and K_2 are both faces of K.

Clearly each of the faces $\Phi(e_1), K_1, K_2$ and K itself are A-invariant. Indeed, they are precisely all the nonzero A-invariant faces of K. To see this, let F be any nonzero A-invariant face of K. If F contains an extreme vector of the form $A^i(e_2 - e_4)$ for some $i \geq 0$, then F will contain all the subsequenct vectors $A^k(e_2 - e_4)$ for $k = i+1, i+2, \cdots$ and hence a relative interior vector of K_1; thus F includes K_1. Similarly, F includes K_2, if F contains an extreme vector of the form $A^i(e_2 + e_3 + e_4)$ for some $i \geq 0$. But the extreme vectors of K are (up to multiples) precisely the vectors e_1 and $A^i(e_2 - e_4)$, $A^i(e_2 + e_3 + e_4)$, $i = 0, 1, 2, \cdots$. With these observations, by considering the possible extreme vectors that F may have, we readily see that F must be one of the faces $\Phi(e_1), K_1, K_2$ or K.

Note that K is A-invariant join-reducible, as $K = K_1 \bigvee K_2$. Also each of the faces K_1, K_2 does not contain in its relative interior a generalized

58

eigenvector of A. So, $\Phi(e_1)$ is the only semi-distinguished A-invariant face of K, and hence, with $\lambda = \rho(A)$, condition (b) of Theorem 7.1 is satisfied trivially. However, as we are going to show, in this case we have $m_{\rho(A)} = 2$, so that condition (a) of Theorem 7.1 is not satisfied. Thus, this example shows that in general conditions (a) and (b) of Theorem 7.1 are not equivalent.

Clearly, the vector $e_2 - e_4 + A^2(e_2 - e_4)$ $(= (2, 2, 0, -(1 + \alpha^2))^T)$ belongs to relint K_1. Similarly, the vector $e_2 + e_3 + e_4 + A^2(e_2 + e_3 + e_4)$ $(= (2, 2, 2, 1 + \alpha^2)^T)$ belongs to relint K_2. Hence, their sum, which is $(4, 4, 2, 0)^T$, belongs to int K. The latter vector is, in fact, also a generalized eigenvector of A corresponding to $\rho(A)$ of order two. This shows that $m_{\rho(A)} = 2$, as desired.

Since $\Phi(e_1)$ and K are the only A-invariant faces that contain in their relative interiors a generalized eigenvector of A, with $\lambda = \rho(A)$, condition (c) of Theorem 7.2 is satisfied. However, condition (b) of Theorem 7.2 is not satisfied (with $\lambda = \rho(A)$), as K is not semi-distinguished A-invariant. Thus, this example shows that, in general, for the conditions (b), (c) of Theorem 7.2, the implication (c)$\Longrightarrow$(b) does not hold.

Also note that in this example there does not exist a semi-distinguished A-invariant face F such that $\mathrm{sp}_A(F) = \mathrm{sp}_A(K)$, though K contains in its interior a generalized eigenvector of A. So the converse of Remark 6.5 is not true.

Example 8.2. Take any fixed positive real number α less than 1, and let

$$A = \begin{bmatrix} 1 & 1 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & \alpha \end{bmatrix}.$$

Let K_1, K_2 be the convex cones of $\mathbb{R}^4$ given by:

$$K_1 = \mathrm{pos}\,\{e_1, e_4, A^i(e_2 - e_4), i = 0, 1, 2, \cdots\},$$
$$\text{and}\quad K_2 = \mathrm{pos}\,\{e_1, e_4, A^i(e_2 + e_3 + e_4), i = 0, 1, 2, \cdots\}.$$

Also, let $K = K_1 + K_2$. Then K is a proper cone of $\mathbb{R}^4$ and we have $A \in \pi(K)$. (Note that the cones K_1, K_2 considered here are each obtained

from the corresponding cones in Example 8.1 by adjoining the extra extreme ray $\Phi(e_4)$, whereas the matrix A is the same as before.)

Using an argument similar to the one used in Example 8.1, one can readily show that the nonzero A-invariant faces of K are precisely $\Phi(e_1), \Phi(e_4)$, $\Phi(e_1 + e_4), K_1, K_2$ and K itself. Among these faces, only the faces $\Phi(e_1), K_1$ and K have the property that it contains in its relative interior a generalized eigenvector of A corresponding to $\rho(A)$. Furthermore, $\Phi(e_1)$ and K_1 are the only semi-distinguished A-invariant faces associated with $\rho(A)$, and $\mathrm{sp}_A(K_1) = \mathrm{sp}_A(K) = (1, 2)$. Thus, with $\lambda = \rho(A)$, condition (c) of Theorem 6.4 is satisfied. However, condition (a)(i) of Theorem 6.4 is not satisfied, as K cannot be written as the join of semi-distinguished A-invariant faces associated with $\rho(A)$. Also note that K_2 is a nonzero A-invariant face associated with $\rho(A)$, but there does not exist a semi-distinguished A-invariant face F included in K_2 such that $\mathrm{sp}_A(F) = \mathrm{sp}_A(K_2) = (1, 2)$. So condition (b)(i) of Theorem 6.4 is also not fulfilled. Thus, this example shows that, in general, condition (c) of Theorem 6.4 does not imply condition (a) nor condition (b) there.

Example 8.3. Let $A = J_2(1) \oplus J_1(1) \oplus J_1(\alpha) \oplus J_1(1)$, where $0 < \alpha < 1$. On $\mathbb{R}^5$ define the following cones:

$$
\begin{aligned}
K_1 &= \mathrm{pos}\,\{e_1, A^i(e_2 - e_4), i = 0, 1, 2, \cdots\}, \\
K_2 &= \mathrm{pos}\,\{e_1, A^i(e_2 + e_3 + e_4), i = 0, 1, 2, \cdots\}, \\
K_3 &= \mathrm{pos}\,\{e_1, A^i(e_2 + e_4 + e_5), i = 0, 1, 2, \cdots\},
\end{aligned}
$$

and $K = K_1 + K_2 + K_3$. Clearly K_1, K_2 and K_3 are each closed, pointed cones. Furthermore, it is easy to verify that

$$
K_1 \bigcap (-K_2) = \{\mathbf{0}\} \quad \text{and} \quad (K_1 + K_2) \bigcap (-K_3) = \{\mathbf{0}\}.
$$

It follows that K is a proper cone of $\mathbb{R}^5$.

It is not difficult to show that K_1, K_2 and K_3 are all faces of K. In addition, we can also show that $K_1 + K_2$ and $K_1 + K_3$ are also faces of K.

(Whether $K_2 + K_3$ is a face of K is not obvious to us, but we do not need that for our purposes.) Then clearly $K_1 + K_2 = K_1 \vee K_2$ and $K_1 + K_3 = K_1 \vee K_3$.

Clearly, we have $A \in \pi(K)$. It is not difficult to show that the nonzero A-invariant faces of K are precisely $\Phi(e_1), K_1, K_2, K_3, K_1 + K_2, K_1 + K_3, K$, and possibly $K_2 + K_3$. Among these A-invariant faces of K, only $\Phi(e_1)$ is semi-distinguished A-invariant. Note that $K_1 + K_2, K_1 + K_3$ are noncomparable A-invariant faces, each containing in its relative interior a generalized eigenvector of A corresponding to $\rho(A)$. So, in this case, with $\lambda = \rho(A)$, condition (d) of Theorem 7.2 is satisfied, but not condition (c). This shows that for conditions (c), (d) of Theorem 7.2, in general, we do not have (d)$\Longrightarrow$(c).

9. Open questions

In trying to improve or better understand the result of Theorem 6.6, we pose the following question.

Question 9.1. Let K be a proper cone whose dual cone K^* is a facially exposed cone. Is it true that for any $A \in \pi(K)$, we have the following?

(i) For any nonzero A-invariant face F of K, F is semi-distinguished A-invariant if and only if $\mathrm{sp}_A(F) \succ \mathrm{sp}_A(G)$ for all A-invariant faces G properly included in F.

(ii) There exists in K a generalized eigenvector of A corresponding to $\rho(A)$ of order $\nu_{\rho(A)}(A)$.

(iii) For any A-invariant face F which contains in its relative interior a generalized eigenvector of A, there exists a semi-distinguished A-invariant face G included in F such that $\mathrm{sp}_A(G) = \mathrm{sp}_A(F)$.

Question 9.2. Let K be a proper cone with the property that the dual cone of each of its faces is a facially exposed cone. Is it true that, for any $A \in \pi(K)$ and any distinguished eigenvalue λ of A, condition (a) of Theorem 6.4 is always satisfied?

We do not know the answer to Question 9.2 even when K is a perfect cone or is equal to $P(n)$ for some positive integer n. If the answer is in the negative, then it will follow that conditions (a) and (b) of Theorem 6.4 are logically independent (cf. Theorem 6.6 and the discussion following Remark 6.5).
