Katija & Dabiri (2009) looked at transport by jellyfish:

`play movie`

There was quite a stir at the time about biomixing and its possible role in the ocean.

The idea goes back to Walter Munk in the 60s, who dismissed it. Revived by Bill Dewar and others in the 00s.

Since then the consensus is that the effect is negligible, in large part due to stratification (Visser, 2007; Wagner *et al.*, 2014).

Still could have important local impact, and is more relevant for micro-organisms.

Around the same time precise experiments were being made, most notably in the Gollub and the Goldstein groups:
play movie

Guasto, J. S., Johnson, K. A., & Gollub, J. P. (2010). *Phys. Rev. Lett.* **105**, 168102

Displacement by a moving body

Use drift trajectories to model mixing induced by swimmers:

Fɪɢ. 1.
Fluid flowing past a fixed cylindre.

Fɪɢ. 2.
Paths of particles of the fluid when a cylinder moves through it.

Maxwell (1869); Darwin (1953)

Dilute theory: swimmers repeatedly 'kick' fluid particles. play movie

Thiffeault, J.-L. & Childress, S. (2010). *Phys. Lett. A,* **374**, 3487–3490

Lin, Z., Thiffeault, J.-L., & Childress, S. (2011). *J. Fluid Mech.* **669**, 167–177

- Find the distribution of displacements for a single swimmer.
- The sum of displacements for many swimmers is the convolution of single-swimmer displacements.
- In Fourier space (characteristic function), the convolution is a simple product, but we must then take an inverse transform.
- Usually this inverse transform is approximated using the Central Limit Theorem, but here we must evaluate it explicitly because of the short times involved.
- Care must be taken when going to the infinite-volume limit.

R_λ^N is the random particle displacement due to N swimmers;
The mean-squared-displacement is

$$\langle (R_\lambda^N)^2 \rangle = n \int_V \Delta_\lambda^2(\boldsymbol{\eta}) \, \mathrm{d}V_{\boldsymbol{\eta}}$$

with

- $n = N/V$ the number density of swimmers
- λ the path length of swimming
- Δ_λ the fluid displacement (drift)
- $\boldsymbol{\eta}$ the initial fluid particle position

Crucial point:

If the integral grows linearly in λ, then the particle motion is diffusive.

Plot of the integrand:
Left: support grows linearly with λ (typical of near-field). Thiffeault & Childress (2010)

Right: 'uncanny scaling' $\Delta_\lambda(\boldsymbol{\eta}) = \lambda^{-1} D(\boldsymbol{\eta}/\lambda)$ (typical of far-field stresslet). Lin *et al.* (2011); Pushkin & Yeomans (2013)

We can go further with this model and find an expression for the full probability density, in the form of an inverse Fourier transform:

$$p_{X_\lambda}(x) = \frac{1}{2\pi} \int_{-\infty}^{\infty} \exp\left(-n\,\Gamma_\lambda(k)\right) e^{-ikx}\, dk$$

The limit taken is effectively a continuous convolution of individual distributions.

The rate function is

$$\Gamma_\lambda(k) := \int_V \left(1 - \operatorname{sinc}(k\Delta_\lambda(\boldsymbol{\eta}))\right) dV_{\boldsymbol{\eta}}\,.$$

Thiffeault, J.-L. (2015). *Phys. Rev. E,* **92**, 023023

A model swimmer

This is as far as we can go without introducing a model swimmer.

We take a squirmer, with axisymmetric streamfunction:

$$\Psi_{\sf sf}(\rho, z) = \tfrac{1}{2}\rho^2 \, U \left\{ -1 + \frac{\ell^3}{(\rho^2 + z^2)^{3/2}} + \tfrac{3}{2} \frac{\beta \ell^2 z}{(\rho^2 + z^2)^{3/2}} \left(\frac{\ell^2}{\rho^2 + z^2} - 1 \right) \right\}$$

See for example Lighthill (1952); Blake (1971); Ishikawa *et al.* (2006); Ishikawa &
Pedley (2007); Drescher *et al.* (2009)

We use the stresslet strength $\beta = 0.5$, which is close to a treadmiller:
Leptos, K. C., Guasto, J. S., Gollub, J. P., Pesci, A. I., & Goldstein, R. E. (2009). *Phys. Rev. Lett.* **103**, 198103;   Thiffeault, J.-L. (2015). *Phys. Rev. E,* **92**, 023023

Formula for the effective diffusivity from Thiffeault (2015):

$$D_{\text{eff}} = D_0 + \left(0.266 + \tfrac{3}{4}\pi\beta\right) U n \ell^4$$
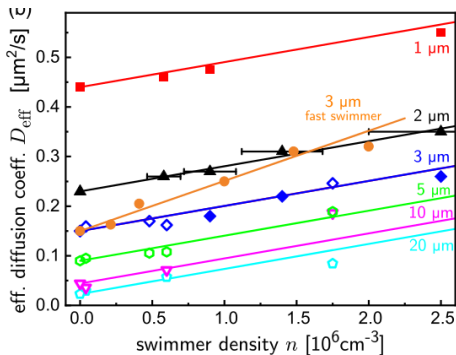

Their experiments are longer and they can see convergence to a Gaussian form, at the rate predicted by the dilute theory.

Ortlieb, L., Rafaï, S., Peyla, P., Wagner, C., & John, T. (2019). *Phys. Rev. Lett.* **122**, 148101

Sphere-flagellum time-dependent swimmer [Peter Mueller] play movie
Map of displacement Δ_λ as a function of initial fluid particle position (X_0, Y_0).

Notice the largest displacements are near the swimmer's body, because of the no-slip boundary condition.

Microswimmers and active particles are often modeled as Brownian particles with a propulsion, using an SDE such as

$$\mathrm{d}X = U\,\mathrm{d}t + \sqrt{2D_X}\,\mathrm{d}W_1$$
$$\mathrm{d}Y = \sqrt{2D_Y}\,\mathrm{d}W_2$$
$$\mathrm{d}\theta = \sqrt{2D_\theta}\,\mathrm{d}W_3$$

in its own rotating reference frame.

In terms of absolute x and y coordinates, this becomes

$$\mathrm{d}x = \left(U\,\mathrm{d}t + \sqrt{2D_X}\,\mathrm{d}W_1\right)\cos\theta - \sin\theta\,\sqrt{2D_Y}\,\mathrm{d}W_2$$
$$\mathrm{d}y = \left(U\,\mathrm{d}t + \sqrt{2D_X}\,\mathrm{d}W_1\right)\sin\theta + \cos\theta\,\sqrt{2D_Y}\,\mathrm{d}W_2$$
$$\mathrm{d}\theta = \sqrt{2D_\theta}\,\mathrm{d}W_3\,.$$

Fokker–Planck equation for the probability density $p(x, y, \theta, t)$:

$$\partial_t p = -\nabla \cdot (\boldsymbol{u}\, p - \nabla \cdot \mathbb{D}\, p) + \partial_\theta^2 (D_\theta\, p)$$

where the drift vector and diffusion tensor are respectively

$$\boldsymbol{u} = \begin{pmatrix} U \cos\theta \\ U \sin\theta \end{pmatrix}$$

$$\mathbb{D} = \begin{pmatrix} D_X \cos^2\theta + D_Y \sin^2\theta & \frac{1}{2}(D_X - D_Y) \sin 2\theta \\ \frac{1}{2}(D_X - D_Y) \sin 2\theta & D_X \sin^2\theta + D_Y \cos^2\theta \end{pmatrix}.$$

Note that $\nabla := \hat{\boldsymbol{x}}\, \partial_x + \hat{\boldsymbol{y}}\, \partial_y$ (no θ).

For any fixed volume V we have

$$\partial_t \int_V p \, \mathrm{d}V = - \int_V \left(\nabla \cdot (\boldsymbol{u} \, p - \nabla \cdot (\mathbb{D} \, p)) - \partial_\theta^2 (D_\theta \, p) \right) \mathrm{d}V$$

$$= - \int_{\partial V} \boldsymbol{f} \cdot \mathrm{d}\boldsymbol{S}$$

where ∂V is the boundary of V, and the flux vector is

$$\boldsymbol{f} = \boldsymbol{u} \, p - \nabla \cdot (\mathbb{D} \, p) - \hat{\boldsymbol{\theta}} \, \partial_\theta (D_\theta \, p).$$

Thus, on the reflecting (impermeable) parts of the boundary we require the no-flux condition

$$\boldsymbol{f} \cdot \boldsymbol{n} = 0, \quad \text{on} \quad \partial V_{\mathsf{refl}}$$

where $\boldsymbol{n}$ is normal to the boundary.

Denote by $y_*(\theta)$ the vertical coordinate of a swimmer with orientation θ when it touches the wall.
play movie

Convex swimmer touching a horizontal wall at $y = 0$:
We call $y_*(\theta)$ the wall distance function. The swimmer's y coordinate must satisfy $y \geq y_*(\theta)$, otherwise the swimmer is inside the wall.

$$y_*(\theta) = \sqrt{a^2 \sin^2 \theta + b^2 \cos^2 \theta} - \tfrac{1}{2}a \sin \theta$$

play movie

Drift is $U \sin \theta \, \hat{\boldsymbol{y}}$; no-flux condition forces swimmer to align with the wall.
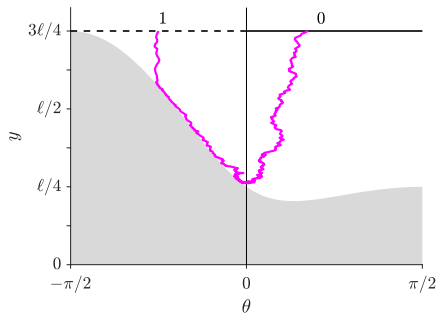

Once the particle crosses $\theta = 0$ (parallel to wall), it is pushed upward by the drift.

play movie

For example, one application of this configuration space formalism is to the transport of microswimmers in a narrow channel:
A swimmer will turn around once in a while, effectively undergoing a 1D random walk. What is the effective horizontal diffusion coefficient?
Configuration space for the needle in of length $\ell = 1$ in a channel of width $L = 1.05$. (x not shown.)

A point in this space specifies the position and orientation of the swimmer.

The Fokker–Planck equation is challenging to solve because of the complicated boundary shape.

Tractable limit $D_\theta \ll 1$ (small rotational diffusivity)

Get a (1+1)D PDE for $p(\theta, y, t) = P(\theta, T)\, e^{\sigma(\theta)y}$

$$\boxed{\partial_T P + \partial_\theta(\mu(\theta)\, P - \partial_\theta P) = 0} \qquad T := D_\theta\, t$$

The shape of the swimmer enters through drift $\mu(\theta)$.

The natural invariant density for the swimmer satisfies

$$\partial_\theta(\mu(\theta)\, \mathcal{P} - \partial_\theta \mathcal{P}) = 0.$$

which can be solved semianalytically for some simple shapes.
For an asymmetric swimmer, the invariant density has a net rotational drift even at equilibrium.

$$L = 2.00$$
play movie

Whenever the swimmer goes through one of the bottlenecks below, this corresponds to a reversal of swimming direction.

The mean reversal time τ_{rev} is

$$\tau_{\mathrm{rev}} = \frac{1}{4D_\theta} \int_0^\pi \frac{\mathrm{d}\vartheta}{\mathcal{P}(\vartheta)}$$

where $\mathcal{P}(\theta)$ is the marginal invariant probability density for the swimmer.

Intuitively, small $\mathcal{P}$ corresponds to "bottlenecks" that dominate the reversal time.

For the needle swimmer,

$$\tau_{\mathrm{rev}} \approx \frac{\pi}{2\beta D_\theta}\, \mathrm{e}^\beta, \qquad \beta = U\ell/4D_Y.$$

From this we get an effective diffusivity

$$D_{\mathsf{eff}} \approx \tfrac{1}{2}\tau_{\mathrm{rev}}\, U^2$$

Conclusions

- Transport and mixing of, and caused by, microswimmers is a fertile area of study.

- The interaction of microswimmers with boundaries is a huge topic, and I apologize for not doing justice to the literature today, for lack of time.

- Our focus is on modeling interactions using the rich concept of configuration space, involving all the degrees of freedom of the swimmer constrained by boundaries.

- Steric interactions are part of the boundary conditions rather than modeled as a potential.

- Can add lots of effects to F–P equation:
  - hydrodynamics
  - interaction forces
  - deformable body and flagella
  - 3D
